It is evident, when we consider the numerous possible sources of trouble leading to faulty cells, that the making of a good dry cell requires care. Amalgamation of the zinc is occasionally resorted to, but it is doubtful whether material advantage accrues through the use of mercury in the dry cell. It is customary to consider the carbon rod as the cathodic electrode, and there are, therefore, arguments favouring the large corrugated and fluted shapes over the smaller cylindrical shapes, in that greater active electrode surface is thereby attained. It is doubtful, however, whether the surface of this rod is to an appreciable extent an active electrode surface. It makes contact with and is surrounded by a mass of material—carbon, graphite and manganese—possessing metallic conductivity even though moistened by electrolyte. It would, therefore, be more accurate to consider the active cathode surface as that portion of the mixture just within the paper. While this may be the main cathode surface, it is not exclusively so, and the active surface progresses inward as the action of the cell goes on. The cathode is a compound one, consisting of an intimate mixture of conductive carbon and graphite in contact with manganese oxide, and the E.M.F. of the cell is the summation of the electrode potentials, 0·56 volt for the zinc and about 1 volt for the carbon-manganese oxide mixture, or a combined voltage of 1·56. While the cell delivers current to the external circuit this voltage decreases, the rapidity depending upon the amount of current drawn. If it were not for the manganese dioxide the drop in the voltage would be very rapid, and the value of the cell is therefore dependent largely upon the active manganese oxide or depolariser. This manganese oxide is consumed. As commonly stated, it is reduced to Mn_2O_3, and in undergoing this change it becomes inactive both as a depolariser and as a conductor. It is probable that the MnO_2 possesses sufficient metallic conductivity to contribute something to the conductivity of the cell, and when changed to the lower oxide it loses this conductivity. It thus becomes inert and occupies valuable space. It is natural to assume that the MnO_2 in the outer portions near the paper is the first to become reduced, the action progressing inward to a certain depth, this depending upon various factors, such as the intimacy of contact between the carbon and MnO_2, the purity, fineness and porosity of the latter, &c. If the MnO_2 possesses metallic conductivity and makes contact with conductive carbon and both are moistened with electrolyte, there is a possibility that a certain amount of chemical action occurs owing to the voltaic couple thus produced.

A study of what actually takes place, chemically and electrically, inside of the dry cell while in action, and while standing in storage, offers an excellent subject for analytical research. While the chemical reactions which take place in the dry cell or other cells of the Leclanché type are frequently explained in a simple manner in text-books, a careful study will show that simplicity does not exist.

It is very commonly believed that the increase in resistance is due to the drying out of the cell, but the drying is of very minor importance as compared with other factors. One of these is the increase in resistance due to the partial reduction of the MnO_2. Another is the accumulation, on the surface between the paper and the zinc, of non-soluble impurities of the zinc and the various basic salts and double salts resulting from the electrolytic corrosion. When a cell is first made up the paper is saturated with a solution of zinc and ammonium chlorides. More zinc chloride is added as a result of the corrosion of the zinc. The increasing concentration of the $ZnCl_2$ in the presence of the ammonium chloride gives just the conditions which are needed for the production of various double chlorides, some of which are much less soluble than the single chlorides. These insoluble double chlorides occupy the pores and spaces in the paper, crowding out the electrolyte and increasing the resistance. If ammonia is liberated, it may react with the $ZnCl_2$ to form a precipitate of ZnOH, which likewise clogs the cell, unless sufficient ammonia be present to re-dissolve this precipitate. That this clogging action occurs at the paper and proceeds inward toward the carbon rod is evident, since in taking apart a run-down cell there is usually found a hard crust of ⅛ in. or more in thickness just inside the paper.

It is no doubt true that improvement in dry cell construction must come through reducing this accumulation of insoluble non-conductive materials. It may be suggested that this precipitation due to double chlorides might be delayed by using only NH_4Cl in the electrolyte to

Digitized by Google

begin with, and, in fact, a somewhat greater ampere-hour output can be obtained in this way. But it involves the more serious disadvantage of shortening the life of the cell on open circuit. The presence of $ZnCl_2$ in the electrolyte decreases in marked degree the local action.

There is no doubt that marked improvement has been made in dry cells during the past few years, and there is no reason to believe that perfection has yet been approached. The field for research in the study of this important device has by no means been fully occupied. From the technical point of view the need for, and possibility of, improvement are equally great. The common and grossly inadequate methods of rating dry cells in terms of the number of miles they will run the ignition device on automobiles, or the number of months they will stand up on telephone service, or the number of sparks that they will produce, all of which are dependent upon the kind of device and the nature of the same in connection with which they are used, should give way to rating by energy output. This can only be done after determining and generally adopting the standard methods for conducting tests.

DISCUSSION.

Mr. CARL HERING said that the Paper stated that the E.M.F. of the cell was the sum of the two electrode potentials, 0·56 volt for the zinc and about minus 1 volt for the carbon-manganese oxide mixture, giving the combined voltage as 1·56. It seemed to him that there must be something wrong in this. It credited the greater part of the energy to the reduction of the manganese oxide, whereas the energy came chiefly from the oxidation of the zinc. He would like to ask, therefore, how it was determined; If it was determined by measurement, was not the method faulty? It seemed that no one had yet been able to measure the absolute single potential of an electrode by a method which was really beyond question. Calculation would show that the zinc gave the greater part and the manganese oxide the lesser part of the energy. Generally, the energy contributed by the depolariser was very small. The Paper also said it would seem better to reduce the formation of the insoluble compounds—that is, that it would seem better to have them soluble. The question arose whether that was really desirable. There was only a very small amount of water in the battery, and that small amount had to do a great deal of work: it seemed to him that if the products were soluble rather than insoluble, the water would be used up more rapidly, by having to hold in suspension the products that were formed; it would, therefore, not be available any longer as water. If this were correct, it seemed to him that it was rather a desirable thing to arrange to have the chemical products formed insoluble, so that they would deposit out and leave the water there to keep the cell wet.

Mr. CHARLES L. PARSONS asked if in their experiments with dry cells the author had made any experiments in the use of bromates as depolarising and oxidising agents. In some work done during the last year bromates certainly showed wonderful oxidising power at low temperature. He would be interested to know whether these bromates had been worked with to any extent in dry cell construction.

Prof. BURGESS, in reply, said as to bromates, chlorates and many other oxidising compounds, the use of these in most instances would increase the voltage of the cell and increase the amount of current output, but in general his experience had been that the soluble oxidising agents were detrimental to the life of the cell—that is, they increased the local action.

CONTACT DIFFERENCE OF POTENTIAL IN A MAGNETIC FIELD.*

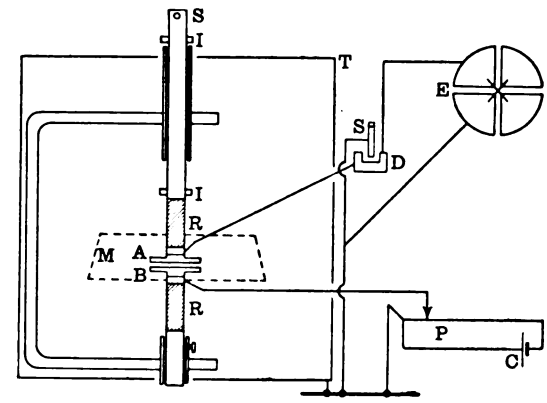
BY E. P. ADAMS.

Summary.—The author first discusses the theory of the contact difference of potential between pairs of metals, and then describes some experiments carried out two years ago which showed no change in the potential due to the introduction of a magnetic field. More recent experiments of M. Posejpal, however, show such a change: but these experiments are considered by the present author to be indecisive.

It seems well established that the contact difference of potential between metals in air is a chemical effect, the result of differential chemical action between the metals and condensed air films on their surfaces. There is, however, another way of looking at the subject. The fundamental thing to be explained is that the potential of an insulated metal differs from that of the surrounding air; and that this difference of potential varies from metal to metal. Let us assume that each unit area of the surface of the metals emits in unit time N electrically-charged particles, each of mass m and charge e. The metal is further supposed to be coated with a thin film of condensed air, or other substance, with the very high transverse electric resistance R per unit surface. The charged particles must be supposed to be emitted from the metal with an initial velocity sufficient to carry them through the film. A difference of potential V is thus set up between the two sides of the film. In the steady state the electric current due to the flow of charged particles from the metal through the film is balanced by the conduction current, the result of the difference of potential V and the conductivity 1/R of the film. Therefore, $Ne = V/R$, or $V = NeR$. Both N and R may be supposed to vary with the metal; thus each insulated metal will be at a definite potential above or below that of the surrounding air.

Suppose next that the metal in the form of a disc is placed in a magnetic field parallel to its plane. The charged particles will tend to describe circular paths whose radius of curvature is given by $mv^2/\rho = Hev$, v being the velocity of the particle and H the magnetic force. If this radius of curvature is small enough some of the particles will be prevented from getting through the film; the difference of potential between the two sides of the film will be diminished, and thus the contact difference of potential between a pair of metals, which is all that can be measured, will be changed. About two years ago the writer made some experiments to verify this, but the results were decisively negative (the sensitiveness of the method employed was such that a change of 0·001 volt in the contact difference of potential could have been observed). Very recently, however, M. V. Posejpal* has published the results of some experiments, a part of which bear upon this same problem. Contrary to the results of the writer, M. Posejpal, who used a different method, finds that the contact difference of potential between iron and zinc is changed in a magnetic field.

The compensation method devised by Lord Kelvin was employed by the writer. In the accompanying diagram A and B represent the two metal discs the contact difference of potential between which is to be measured. These are screwed on to the brass ends of the hard rubber insulators R, R, which are carried on brass rods, and these in turn freely slide through fixed brass tubes, as shown. The lower rod is fixed in position, its height being adjusted by means of a set screw. The limits of motion of the upper rod are controlled by the adjustable collars I, I.



The upper disc is permanently connected to one pair of quadrants of the electrometer E. By means of the mercury key D, this pair of quadrants may be connected to earth. When the rod S is raised, the earth connection is broken. The other pair of quadrants is connected to earth. The lower disc B is connected to the slider of the potentiometer P, so that it may be kept at any desired potential. Strings are attached to S, S by means of which the earth connection of the first pair of quadrants may be broken and the upper disc raised at the observing telescope. The determination of the contact difference of potential is made as follows: the electrometer quadrants being earthed, the two discs are brought close together, but not touching. Electrically they are of course in contact. The earth connection is then broken and the upper disc raised. A deflection of the electrometer needle, in general, results. The potential of the lower disc is then changed until on repetition of the above process no deflection of the electrometer results. The potential applied to the lower disc is then the contact difference of potential between the two discs.

Experiment showed that when the contact difference of potential between the discs was balanced by the potential applied to the lower, a change of 0·001 volt in the latter produced a distinct deflection. The pole-pieces of the electromagnet, one of which is shown in section at M, projected through holes cut into opposite sides of a zinc box T, which completely shielded the interior. As a further precaution against outside electrostatic disturbances the pole-pieces themselves were earthed. The electrometer connections were run through earthed brass tubes. The electrometer used was of the Dolezalek type, and had a sensitiveness of about 8,000 divisions per volt, and the needle was kept at a potential of about 80 volts by means of a battery of small storage cells.

The discs used were made of iron, zinc, and gold- and platinum-

* Abstract of an article in the "Physical Review."

* "Annales de Chimie et de Physique," August, 1909.

Digitized by Google

plated brass. After the discs were cleaned and screwed into position the contact difference between them changed rapidly; but after the course of an hour or so it became so constant that no change could be detected during a period of 10 to 15 minutes. During this stage the contact difference was measured, then the magnetic field was applied and the contact difference again measured, and a final measurement was made after the magnetising current was broken. Many repetitions of this were made, using the combinations gold-zinc, platinum-zinc and gold-iron, but in no case was the slightest effect of the magnetic field observed. The magnetic force was measured by a calibrated bismuth spiral and was approximately 4,800 electromagnetic units.

The experiments of M. Posejpal differed in at least three important respects from those just described. In the first place, he used a direct deflection method, instead of a null method, which necessarily involved greater possibility of error. In the second place, the two discs were allowed to come into actual contact with each other before separation. It seems possible that the observed effects resulted from this actual contact. The contact difference of potential between metals is extremely sensitive to changes in their surfaces. If one of the discs is allowed to fall on the other considerable changes in the contact difference are almost certain to result. The writer has observed that if the initial distance between the two discs was made so small that on dropping the upper disc it touched the lower one, due to a lack of rigidity in the support, a distinct change in the contact difference was found on the next measurement. M. Posejpal found that the contact difference was by no means constant and sought to get correct values by taking the average of many results. Now when a magnetic field is applied this mechanical effect would be altered, particularly in M. Posejpal's experiments, since he used only the combination zinc-iron. The iron, unless very firmly held, would be certain to move in the magnetic field, and thus a secondary effect of the magnetic field on the contact difference of potential might be expected to result. Furthermore, when two unlike metals are separated from contact one would expect a production of frictional electricity, which, of course, would be added to the electricity set free by the true contact difference of potential. In the magnetic field, due to mechanical action on the iron, the amount of frictional electricity would be altered, and thus a change in the apparent contact difference of potential would result.

The third difference between the two methods lies in the position of the two discs with respect to the magnetic field. In M. Posejpal's experiment the lower disc remained in the region of strong magnetic force, while the upper disc was pulled into a region of comparatively weak magnetic force. In the writer's experiment, the pole faces of the magnet were of such a size that both discs remained in a fairly uniform field even after the upper disc was raised. Whether an explanation of the results obtained lies in this fact or not can be tested only by experiment. Unfortunately, M. Posejpal does not state the strength of the magnetic field he employed, nor the diameter of the discs. But the large effects he obtained, combined with the comparative insensitiveness of his method (his electrometer gave only 60 divisions for a volt), make it improbable that his positive results were due to using a magnetic field of much greater strength than that used by the writer.

ELECTRIC FURNACE PLANT OF THE UNITED STATES STEEL CORPORATION.*

When in February of last year the United States Steel Corp. adopted the Héroult electric furnace for steel refining, it was decided to erect, as a beginning, two furnaces, each of 15 tons capacity, one at the South Chicago works of the Illinois Steel Co. and the other at the Washburn & Moen plant of the American Steel & Wire Co., at Worcester, Mass. At South Chicago the electric furnace is used for refining molten metal from the Bessemer converter, at Worcester for refining molten metal from the basic open hearth. The object of the combination of the ordinary acid-lined Bessemer converter and the electric furnace (South Chicago) is to produce steel of open-hearth steel quality, or better, at less cost. The object of the combination of basic open-hearth and electric furnace (Worcester) is to produce steel better than the best acid open-hearth steel in quality, at a slightly advanced cost.

The undertaking of the United States Steel Corp. involved some interesting and important novel points. The largest Héroult furnaces installed before that time had a capacity of 5 tons. In the Héroult furnaces of the Steel Corp. this capacity was trebled. Further, the Héroult electric furnace had been used before on a commercial scale with cold charges, and with molten metal from the open-hearth furnaces; but in South Chicago it was adopted for the first time in America on a large scale in combination with the Bessemer converter. Finally, while in the past the Héroult process had been used essentially as a substitute for the crucible steel process for the manufacture of high-grade tool steels, &c., it entered into a much wider field of usefulness at South Chicago and Worcester, where it is used for large-tonnage products, like rails, axles, and wire.

The South Chicago plant has been in continuous operation since May of last year, while the Worcester plant was started in the beginning of this year. The South Chicago plant is perhaps the more interesting of the two, since it includes the more involved metallurgical process of both dephosphorisation and desulphurisation of the steel in the electric furnace, while the metal charged from the basic open-hearth into the electric furnace at Worcester is already largely dephosphorised.

The combination of the electric furnace with the Bessemer converter seems a matter of momentous commercial importance. For a number of years the cry of the consumer has been for better steel for many purposes, like rails, &c. As a result, there has been a decided tendency away from the converter and toward the open hearth. If the electric furnace in combination with the Bessemer converter can make as good or better steel at the same or less cost than the open hearth alone, it means that the electric furnace gives a new lease of life to the converter. From this viewpoint the results obtained with electric refining at South Chicago are of broad commercial significance and importance.

That the Héroult furnace at South Chicago is a commercial metallurgical apparatus and no longer in the experimental stage is proved by the regularity with which the heats follow each other. The furnace is in continuous operation during the whole week, and operation is discontinued only on Sunday. On the average 12 heats are made a day. Figures given for a particular day show that current was on for 18 hours and 5 minutes, so that the intervals between the successive heats amounted to 33 per cent. of the whole time. The average specific energy consumption on that day was 88·4 kw.-hours per 1,000 lb. net weight, or 194·5 kw.-hours per net metric ton. In this case the electric furnace treatment involved both desulphurisation and dephosphorisation. If the charge supplied to the electric furnace is already low in phosphorus, the specific energy consumption is, of course, less. Figures given in this connection show the average specific energy consumption to be 47·2 kw.-hours per 1,000 lb. net weight. Electrical energy is generated by means of gas engines, operated with blast furnace gas, and the two plants of the Steel Corp. at South Chicago, Ill., and Gary, Ind., are electrically connected in parallel. The power generation is highly economical. The charge for energy supply, made to the electric furnace plant, is 0·25d. per kw.-hour consumed.

The regularity of operation which makes the Héroult furnace at South Chicago a thoroughly commercial apparatus is due in no small degree to the simplicity and compactness of construction of the Héroult furnace and the total absence of any complications whatsoever, either electrical or otherwise, with the possible single exception of the electrodes at the top. The simplicity of the construction results in great convenience of repairs of the furnace proper. During the whole period of operation at South Chicago, since May, 1909, there has never been any necessity to stop the Héroult furnace for the sake of repairs. The lining is kept in good condition by throwing some shovels of broken burnt dolomite into the furnace upon the corroded portions of the hearth. This is done between successive heats, and requires not more than a few minutes. The consumption of dolomite for repairs is given as 10 lb. of dolomite per ton of steel. The silica roof has been generally repaired or replaced during the regular stop on Sundays. The last roof, however, lasted 129 heats. The cost of repairs is very low, about 3d. per ton.

As to the electrodes, their consumption is given as averaging 6 lb. per ton of steel, and this figure is stated to be true both for graphite and for amorphous carbon. This item, it is expected, can be very materially reduced in future. The original intention was to use amorphous carbon electrodes, but it was found very difficult to make very large homogeneous carbon electrodes. Graphite electrodes are now doing the service very satisfactorily, but are more costly. The electrodes as used at present are made up of Acheson graphite rods, 48 in. long and 8 in. in diameter. Three such rods are butt-connected to a total length of 144 in., and three such 144 in. rods are arranged side by side to form a single electrode. A water-cooled jacket is provided around each electrode, just above the openings in the roof.

Simply to try what can be done with the electric furnace, a very severe test was made some time ago. The worst kind of scrap (plate scrap, rusty nails, &c., in fact, the sweepings of the works)

*Abstract of an article in "Metallurgical and Chemical Engineering."

Digitized by Google

was used. The specification was to produce steel; C., 0·35 to 0·45; S., 0·04; P., 0·04; Mn., 0·35 to 0·50. The steel produced analysed: C., 0·46; S., 0·037; P., 0·024; Mn., 0.34. There were charged in this test 9,000 lb. hot pig iron, 12,000 lb. rail ends, and 9,000 lb. stove-plate scrap, "the worst stuff to be found." The product was 31,800 lb. of steel. The energy consumption during this remarkable test was 14,450 kw.-hours.

As to the mechanical tests of the steel now being made by the Héroult-Bessemer electric process at South Chicago, the following data were given at the mechanical testing plant of the Illinois Steel Co.: Elastic limit, 35,000 lb. to 47,000 lb.; tensile strength, 60,000 lb. to 70,000 lb.; elongation, 25 per cent. to 30 per cent.; reduction of area, 43 per cent. to 60 per cent. As to the difference between this electric steel and acid open-hearth steel it was stated that the same tensile strength is obtained with the electric steel with lower carbon than with open-hearth steel. For example, an 0·10 C. electric steel averages the same tensile strength as an 0·15 C. to 0·17 C. acid open-hearth steel.

THE NATIONAL TELEPHONE CO. AND THE TRANSFER.

We have received the following lengthy communication from the pen of a gentleman who duly sends us his name, but who desires that his identity should not be disclosed. We have the strongest objection to anonymous communications when they attack an individual or a company, but as the communication is only one of a number, to withhold it on the ground of anonymity would serve no useful purpose, and we have, therefore, given it the necessary space in our columns.

Without any desire or intention to speak for the National Telephone Co., whose directors and officials are quite well able to speak for themselves, we consider that many of the statements by "Telephonist" are either beside the point or demonstrably unfair. The speech delivered by Mr. Franklin at the half-yearly meeting of the National Company we consider to have been a perfectly accurate statement of the company's case, as it affects the shareholders' position, and we cannot understand why the position of the company, financial or otherwise, should be better known to employés and ex-employés than to the directors and leading officials, who have been associated with the company for very many years, and are much more likely to know where the shoe pinches than either a present or past employé. It is perfectly true that the company's stocks and shares are at a considerable premium, and it is also true that friction has arisen over what has been termed the telephone monopoly, but taking the service as a whole, and judging public companies as such bodies must be judged by the public, we deny that the National Company merits any serious attack. The company has worked, as all companies work, for the ultimate benefit of the shareholders, and not being based on philanthropic lines no other course would meet the circumstances. That the company's reserve fund has reached a large total is not a point against the management, but is one, surely, to its credit. Knowing for many years that the period of its existence was limited, the directors have put by a sum for possible and actual depreciation which now amounts to, say, 20 per cent. of its total paid-up capital. This is not, in our opinion, one shilling too much.

With regard to the "water" in the company's capital account, we speak with an outside knowledge of the company's affairs from the very start of the telephone industry, and we venture to say that the amount of water in the capital, under all the circumstances, is small. The company has had many critics, but we do not remember any particular point having been made at any time regarding this alleged "water."

With the question as to how far the company has, since the more imminent expiry of its licence has drawn near, neglected its duty to the public in regard to spending money on capital account, we are not impressed with "Telephonist's" statement. The Post Office authorities have not, as far as we are aware, complained, and complaint lies almost entirely with the Post Office authorities.

We have, as we have said, given space to this letter for the reason that the points are temperately put, and form, as far as they go, a criticism on matters of public interest. The seventh, eighth, ninth and tenth paragraphs deal with matters which are partly *sub-judice* and cannot possibly be discussed at the present stage, as nothing is settled concerning most of them. We sincerely hope that "Telephonist" is in error in his assumption concerning the effect of the present policy of the company and the consequences of the transfer upon the staff. We fear that in so large a transaction as this transfer there has been already and there will be some hardship to individuals, however wisely conceived the arrangements for the staff may be, but that the National Company and the Post Office between them will act fairly by their officials, staff and employés generally is our sincere belief.

The letter referred to is as follows:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been drawn to a statement recently appearing in the Press as a result of a speech by the President of the National Telephone Co. at the half-yearly meeting of that company as to the alleged injustice and hardship which is being caused the shareholders of the National Telephone Co. (Ltd.), by the action of the Government in terminating the licence of the company and transferring the whole of the telephone monopoly to the direction of the Post Office Department.

As an ex-employé of the N.T.C., I desire to encroach upon your valuable space to deal with the facts as they really are and as are probably only known by the employés and ex-employés of the company.

As to the alleged hardship, the present prices of the company's stocks and shares as quoted by this morning's papers, each class of which shows a considerable premium upon the par value, from a financial standpoint is a sufficient answer to any alleged injustice which it has been suggested will be done, and on turning to the recently published report of the company it is seen that a 6 per cent. dividend has been paid on all classes of shares, and further that the reserve fund of the company has reached the enormous sum of £3,705,127, which, when it is considered that the total captial of the company is but £16,000,000, suggests that the possibility of any loss in connection with the sale of the plant has been adequately provided for.

Those who know something of the manner of the formation of the National Telephone Co. as a telephone monopoly and the way in which the various local companies were bought out and the huge sums paid them for "good will" and of the other directions in which the capital of the company has been watered, will be in a position to appreciate the fact that the company's shareholders, instead of fearing a grave loss as a result of the transfer are, on the other hand, in expectation of a considerable appreciation of the value of their holdings which would not have accrued had the company's licence been extended for an indefinite period necessitating the raising of further large amounts of capital to provide for the expansion and replacements of the plant which would have immediately resulted.

As a matter of fact, the shareholders are deserving of but little sympathy in connection with this transfer, as the manner in which they have treated the public and, more especially, the way in which they have made their own staff, to whose exertions and loyalty they owe the present prosperous condition of the company, feel the whole consequence of the altered financial considerations which are necessitated by the near approach of the termination of their licence, renders them rather the subjects for criticism than for sympathy.

It should be understood that as the period for which the company had a licence to conduct the telephone service ends at Dec. 31, 1911, the ordinary preparations which are made by a telephone undertaking for the development of their system to meet the demands of the public for connections must be considerably modified, and whereas in the ordinary course of business the company would be carrying on their constructional works and be providing for the replacement of the more antiquated of their exchanges by the modern central battery system, they are now closing down all these constructional works and dismissing and placing upon "short time" those of their staff who would have been employed upon these very necessary works.

Proposals have been made by the Postmaster-General which, if accepted by the company, would have allowed of the uninterrupted carrying on of such works and have allocated to the company and to the Post Office due proportions of the cost according to the benefit derived by the parties from the new plant erected and the plant replaced, but the shareholders, acting through their board of directors in pursuit of the "cent. per cent.," have refused these offers, and have thereby caused extreme hardship to their staff, many of whom are threatened with years of unemployment after having served the company faithfully for periods of 5, 10 and 20 years, and are also disregarding the public interest, which demands that the telephone system should be intelligently expanded to meet the demands upon it as occasion arises.

In 1912 and 1913 it will be found, unless some immediate action is taken, that the spare plant at the disposal of the Post Office department for new telephone lines will be altogether insufficient to meet the requirements of the trading community if the telephone system continues to expand at the same ratio as during the past five years. In this connection it must be remembered that the time taken to enlarge a telephone exchange or reconstruct underground or aerial line routes varies from 12 months to two years, according to the size and character of the job.

The position of the staff is particularly hard when it is remembered that the telephone industry is a virtual monopoly, and that, therefore, those men who have spent their lives' service in the telephone undertaking who are thrown into the ranks of the unemployed by the policy of the shareholders of the National Telephone Company are rendered, as far as the United Kingdom is concerned, unskilled workers, and thereby help to swell the already over-crowded ranks of the unemployed of this character. A further serious consequence to the country and to the public will result in the fact that when the Postmaster-General is in a position to do the necessary constructional work himself, after 1911, the skilled staff which will be required to take in hand the construction work will have been dispersed, and it will be found impossible to gather together a sufficient number of practical men to satisfactorily cope with the arrears of work due to the present policy of the company.

Digitized by Google

It may be said that the telephone men discharged by the company will be employed by the Post Office, but it is obvious that until such time as the Post Office take into their own hands the telephone system of the country they will not have that work at their disposal upon which the men can be employed. It may be possible after a period of some 18 months for these men to be employed by the department, but at the cost of starvation and broken service during the intervening period.

I think when these things become known to the general public it will appreciate the fact that any sympathy which may be felt in this matter should rather be with the staff than with the shareholders of the company, who are at the present moment causing untold hardship to their hitherto loyal servants, and, what is of course more important to the public, seriously crippling the future efficiency of the British telephone system, upon which the prosperity of the business community, and therefore the country, has become so dependent.—Yours, &c.,

London, Aug. 9. TELEPHONIST.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

An electrical fitter is required for the Gold Coast Government Waterworks. Age between 25 and 40, preferably unmarried. Salary £300 a year, rising to £350 by annual increments of £10, with free single quarters and second-class passage out and home. Applications to Messrs. Middleton, Hunter & Duff, 17, Victoria-street, London, S.W., up to August 18. See also an advertisement.

An electrical engineer is required by the British Westinghouse Electric & Mfg. Co. (Ltd.), Trafford-park, Manchester, for calculating and laying out winding engines and rolling mills. See advertisement.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Candidates must be graduates, and must have had experience in the test room of first-class electrical engineering firm. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

Mr. P. M. Hampshire, A.R.C.S., A.I.E.E., chief assistant in the physics and engineering department at Blackburn Municipal Technical School, has been appointed lecturer and practical instructor of engineering subjects at the Municipal Institute, Walsall, at a salary of £160 per annum, rising by annual increments of £10 to £200.

Mr. Hampshire, who is a native of Leeds, won a Science and Art National College scholarship, valued at £100 per annum and tenable for three years. From college he went to Messrs. Crompton's, at Chelmsford, where he obtained further practical engineering experience, and from there he passed to Faraday House, where he worked in the test room. Then he went to Finsbury Technical College, and for three years was lecturer in electrical engineering subjects. In Sept., 1906, he received his present appointment at Blackburn, where he has had charge of the theoretical and practical classes in mechanical and electrical engineering.

Mr. J. F. Chapman, of Swinton, has been appointed assistant in the mechanical and electrical engineering department of the Halifax Municipal Technical School, and Mr. N. Wolstenholme, of Morecambe, has been appointed lecturer in mathematics.

Mr. A. H. Lawrence, B.Sc., A.M.I.E.E., late of the Sunderland Technical Institute, has been appointed science master at Huish Grammar School, Taunton.

Mr. B. Wood, of the A.E.G., Berlin, has taken up the position of first assistant engineer to Messrs. Staerker & Fischer, the agents of the A.E.G. in Melbourne, Australia.

Mr. C. F. Butler has been appointed resident electrical engineer to the Uitenhage (Cape Colony) Electric Lighting & Power Co.

EDUCATIONAL NOTICES.

University of London, University College.—The 1910-11 session begins on Monday, Oct. 3. Complete courses of study, extending over three years, are arranged in mechanical, electrical, civil and municipal engineering. Students desirous of entering the faculty of engineering with the view of taking a full degree or diploma course must have passed the matriculation examination or some other examination accepted in its stead. Students who have already attained a sufficient standard may enter for a course occupying less than three years, and may obtain a general certificate of engineering after not less than two consecutive sessions. Graduates in science or engineering, or students who have done the work equivalent to a degree, may be admitted to special courses of study or to prosecute original research. Intending students should communicate with the Provost as soon as possible, and in any case not later than Sept. 20. Full particulars from the secretary, Mr. Walter W. Seton, M.A., Gower-street, London, W.C.

King's College (University of London).—In the Faculty of Engineering complete courses of study, extending over three or four years, are arranged in civil, mechanical and electrical engineering for the engineering degrees of the University of London and for the diploma and certificate of the College. There will also be special courses of advanced lectures on "Internal Combustion Engines" and "The Theory and Practice of Construction." The entrance day for new students is Tuesday, Oct. 4.

University of Birmingham.—The session 1910-11 commences on Monday, Oct. 3. The full courses in the engineering department extend over four years, and students who enter after matriculation and who pass successfully the examinations at the end of each year will be entitled to the degree of Bachelor of Science in the branch of engineering to which they devote themselves. The technical engineering classes include lectures on the strength of materials, theory of steam, gas and other heat engines, hydraulics, machine design, strength of structures and distribution of power, design of tools, prime motors, dynamos, &c. The courses in civil engineering cover a wide range. Lectures and demonstrations are given on all branches of electrical engineering and the electrical laboratory work comprises the testing of c.c. and a.c. machinery, instruments, meters, lamps and batteries and insulation and magnetic testing. The courses also include mathematics, physics, chemistry, geology and metallurgy. Syllabus, &c., from the Secretary.

University of Manchester.—The session commences on Oct. 4. Complete theoretical and practical training is given in this university to students preparing for the higher positions in the electrical engineering profession. The subject may be taken as part of the courses preparing for the B.Sc. degree in both the honours schools of engineering and physics. The John Hopkinson laboratories and dynamo house are well equipped, and offer good facilities for educational and research work. Prospectuses from the Registrar.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

Glasgow and West of Scotland Technical College.—The day classes begin on Tuesday, Sept. 27, and the evening classes on Thursday, Sept. 22. The diploma of the College is granted in civil, mechanical and electrical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study for the diploma usually extend over three sessions, and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow after attendance for at least one session upon prescribed University classes. Preliminary examinations begin on Sept. 19. There are new and well-equipped laboratories in the departments of physics, chemistry, mechanics, motive power and electrical engineering, &c., and facilities are afforded for research. Copies of calendar (price 1s. 4d.) and prospectus (gratis) can be obtained from the Secretary.

Digitized by Google

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

Borough Polytechnic Institute.—We have received a copy of "The Borough Polytechnic Institute; its Origin and Development," by Mr. Edric Bayley, M.A., with an introduction by Mr. Sidney Webb. The work is really a record of the history of the rise and development of one of the most useful of London's educational institutions. There is no one more fitted to deal with the interesting history of the Polytechnic than Mr. Bayley, who has been from its start an able and generous supporter of every movement tending to increase the institution's usefulness. The present work, which is a complete record of the leading events in the career of the Polytechnic, is well printed and illustrated, and is published in royal 4to, cloth gilt, by Mr. Elliot Stock at 6s. net.

Sunderland Technical College.—We have received a copy of the prospectus of the day classes at this College for the 1910-11 Session, and also copies of pamphlets giving details of the evening courses.

The head of the electrical engineering department is Mr. W. T. Maccall, M.Sc., A.M.I.E.E., and Mr. G. F. Bellwood is lecturer in telegraphy and telephony. There are also complete courses of instruction in civil, mechanical and marine engineering, mathematics and physics, chemistry, mining, building, naval architecture, commercial subjects, &c. Particulars of the scholarships for apprentice-students in engineering and naval architecture, tenable at the college, are given in a separate pamphlet.

BRITISH NOTES.

Brentwood.—The Lighting committee has been asked to report upon a request for the assent of the Council to an application for a provisional electric lighting order.

Cavan.—The District Council are desirous of being vested with the powers of an urban authority so as to adopt electric lighting for the town of Killeshandra.

Dublin.—On Monday the City Council were informed by the Lighting committee that the electricity department was making satisfactory progress. Between March 31 and June 30 about 170 new consumers were connected, the number for the corresponding three months of 1909 being 92.

The committee state that they are continuing their policy of endeavouring to postpone any extension work not urgently required although sanctioned by the L.G. Board. A portion of the South Circular-road extension (estimated to cost £5,500) will be carried out at once, and as soon as the South Dublin Guardians wire their premises, cables will be extended to the area around the Union premises at a cost of £2,350.

Eastbourne.—From Oct. 1 the following reductions of charges for electric current will take place:—

Where consumption exceeds 10,000 but does not exceed 30,000 units, ½d. per unit; exceeding 30,000 but not exceeding 50,000, ¼d.; exceeding 50,000, ¼d.; flat rate consumers, 5½d. to 5d.; double tariff consumers, night rate charge, 5½d. to 5d.; supply for heating and cooking, 1d. per unit. Where two or more meters are hired by the same consumer in respect of the same premises, the charge for hire of each meter is to be reduced from 10s. to 6s. per annum.

Electric Pumping Plant.—At the meeting last week of J. Grayson, Lowood & Co. (Ltd.) the chairman (Mr. C. B. Stuart Wortley, K.C., M.P.) said the result of the year's working was unfavourable, owing to a continuance of the difficulties with water in the gannister mine at Deepcar. The directors had come to the conclusion that the existing steam arrangements were inadequate, and had decided to instal an electric pumping plant.

Engineering and Machinery Exhibition.—We are informed that the Marquis of Graham, G.V.O., will formally open the Naval, Mercantile Marine, and General Engineering and Machinery Exhibition at Olympia (London, W.) on Sept. 1.

Many of the latest inventions in connection with all branches of engineering practice will be on view for the first time, and machine tool makers are particularly well represented. The exhibitors include several of the leading firms of manufacturers and engineers in London and the provinces, and the exhibits comprise metallurgical processes and raw materials, castings, machine tools, shop tools and appliances, lifts and lifting appliances, mechanical stokers and conveyors, engineers' stores, lighting, sanitary and ventilating apparatus, dockyard plant, and gas, steam and oil engines, &c. Special meetings of several engineering and scientific societies will be held at Olympia during the period of the exhibition. Preparations for the exhibition are well advanced, and the management are aiming at having the show absolutely complete on the opening day. The exhibition will run from Sept. 1 to Sept. 26 inclusive.

Finchley.—The salary of the electrical engineer (Mr. E. Calvert) has been increased to £525 per annum.

A small show room, for the display of electric motors, fittings, &c., is to be opened at the electricity works.

Hereford.—The L.G. Board have sanctioned the borrowing by the Council of £2,000 for mains and £1,500 for services, the period of repayment being 25 years and 15 years respectively.

The Board of Trade have made an order under sec. 6 of the Electric Lighting Act, 1909, to permit the Corporation to supply electricity to residences outside the present area of supply.

Hornsey.—A dispute has arisen between the Council and the North Metropolitan Electric Power Supply Co. in regard to the supply by the company of electricity to a cinematograph theatre in Hornsey but near the Municipal boundary.

The Council suggested that as a matter of general principle as regards supply of electricity to border cases the profit made (as agreed between the Borough Electrical Engineer and the Engineer-in-Chief of the company) should be apportioned between the Hornsey and Tottenham areas according to the rateable values in the respective districts of each of the premises supplied, the non-supplying authority receiving a moiety of the profit earned within its own area. The company, however, do not agree with this suggestion, and the Council are taking counsel's opinion on the position.

Light Railway.—The Board of Trade have confirmed the Llanelly and District Light Railways (Revival and Extension of Time) Order, 1910, and the Bacup Corporation Light Railway Order, 1910.

Lydney (Glos.)—The Rural Council have authorised Chepstow Electric Light & Power Co. to supply certain houses at Tutshill with electric current by overhead cables, provided the rights of the Gloucestershire Electric Power Co. are not interfered with, and that, if required, the cables are removed on six months' notice.

Municipal Wiring.—A deputation from the local contractors recently waited upon Dundel Town Council with regard to the proposal of the electricity department to support the Municipal Electrical Association in the steps they were taking to secure powers for local authorities to supply electrical fittings and wires on consumers' premises.

The city electrical engineer (Mr. H. Richardson) pointed out that it was an illogical position to allow the gas department to supply fittings, &c., while they denied the same privilege to the electricity department.

Mr. LOWDEN, for the deputation, contended that if the Council obtained powers to hire out motors, &c., and to do wiring and other work it would diminish private contractors' business. These traders were ratepayers, and were entitled to the protection of the Council. They denied absolutely the statement put out from the electricity department that only 10 per cent. of the increase in business was due to contractors' canvassing, while 90 per cent. was due to the department's canvassers. The combined capital of the local contractors was £50,000, and they employed 218 men. Gas and electricity were not on the same footing. So far as heating and cooking were concerned, electricity was a luxury, and therefore there was not the same excuse for the Corporation to go in for trading.

Mr. RICHARDSON said that the various corporations who had not obtained these powers would very soon be severely handicapped if they did not do so. He denied that electricity was a luxury; it was a necessity. It had never been a luxury to the same extent as gas had been in its early days. As to the percentage of new business brought in by private and corporation canvassers, the real figures were 92 per cent. brought in by corporation canvassers, and only 8 per cent. by contractors' canvassers. If the corporation ordered him to drop the present policy of the department, then, of course, he could not be expected to have any responsibility for its success.

An amendment to refer the matter to the committee for further consideration was carried.

Wimbledon Council have agreed to make a contribution (not to exceed £25) towards the expenses of the movement for obtaining Parliamentary powers to authorise all municipal electricity undertakers to provide, let for hire, and fix, repair and remove (but not manufacture) electric fittings, motors and other apparatus for lighting and power.

Barnes Council have referred back a recommendation to contribute a sum (not to exceed £50) towards the expenses of promoting the bill suggested by the Municipal Electrical Association.

Nelson.—The Council have agreed to supply electricity in bulk to Brierfield Council until March 31, 1914, and application is to be made to the Board of Trade for an order authorising the supply.

Digitized by Google

New Acts of Parliament.—Royal Assent has been given to the following New Acts of Parliament :—

Mines (Rescue and Aid), Electric Lighting Orders Confirmation (Nos. 1, 2 and 4), Tramways Orders Confirmation, Metropolitan District Railway, London United Tramways, Bradford Corporation, Middlesbrough Corporation, Rhondda District Council (Tramways Extensions, &c.)

Newcastle-on-Tyne.—The Tramways committee recommend the Corporation to obtain Parliamentary powers to construct additional tramways, including extensions of the present system from Scotswood Bridge to Blaydon, Lemington and Newburn, extensions at Heaton, and in all probability to the sea coast via Benton. Powers will be taken for opening up these districts by trackless trolley cars and then, if desirable, by the ordinary system.

Newspapers and the Law of Libel.—We can wish nothing but success to the efforts of Mr. Walter Judd (Messrs. Heywood & Co. (Ltd.) in his efforts to secure an amendment of the law of libel. As things stand at present (as we very well know) any impecunious plaintiff, even with an imaginary grievance and with the aid of a solicitor ready to undertake speculative work, can cause heavy loss of time and money to the proprietors of newspapers and particularly of trade journals. Mr. Judd will have rendered good service to the Press if he can secure the amendment of the law he seeks. We fear, however, that he has an uphill task. Our experience is that juries are more disposed than judges to sympathise with the newspaper press and its trials.

Presentations.—On July 26 Mr. F. J. Walker, general manager and secretary of the St. James's & Pall Mall Electric Light Co., was entertained at dinner (at the White City, London), and presented by Mr. Frank Bailey (on behalf of the members of the Association of Chief Officials of London Electric Supply Companies) with a personally signed memento engrossed on vellum, in recognition of the active part taken by Mr. Walker in securing combined action by the London electricity supply undertakers in protecting their interests, and opposing projected competitive electric power schemes.

The members present included Mr. E. Cunliffe Owen, C.M.G., Mr. H. B. Renwick, Mr. E. Wilmot Seale, Sir Alexander Kennedy, and others.

Mr. T. G. Gregory, who has relinquished his position with the Mansfield Tramway Co., has been presented by the staff with a smoker's cabinet.

Provisional Order Revocation.—The Board of Trade have revoked the Gainsborough Electric Lighting Order, 1904, as from July 22.

Sheffield.—The Electric Light committee recommend the Corporation to adopt a revised scale of discounts for consumers of the electricity department.

To any consumer who uses electricity for lighting as much as possible throughout the year during daylight or long hours, mostly when the output is not at its maximum, and provided that the consumption (based on the estimated maximum demand) does not fall below 100 units per annum per 60-watt lamp or equivalent, a discount of 50 per cent. from the tariff of 4d. per unit.

Accounts will be rendered weekly, monthly or quarterly, at the option of the committee, and the discounts will be adjusted according to the average daily rate of consumption as shown between successive readings. No discount will be allowed unless the account is paid before the next account is due.

The committee reserve the power, in special cases where they deem it an advantage so to do, to make such terms as they think fit, provided, of course, that in any such case similar terms shall be allowed to other customers in similar circumstances.

Wimbledon.—The L.G. Board has sanctioned the borrowing by the Council of £3,400 for mains, £1,600 for house services and £1,600 for meters.

The Council offer to supply Mr. J. B. Mulholland (owner of theatre, lock-up shops, &c., now being erected at the junction of Merton-road) with energy for incandescent lighting and for arc lamps, limelights and similar apparatus at 2½d. per unit, provided a minimum consumption of 30,000 units per annum is guaranteed. Energy will also be supplied to a skating rink between 4 and 9:30 p.m. at the ordinary lighting rates and at other times at 1d. per unit.

Wireless Telegraph Notes.—We learn that the trials of the recently established wireless telergaph station at Cadiz have given satisfactory results, telegrams having been exchanged between Teneriffe (Canary Islands) and the Eiffel Tower, Paris. The electrical staff are satisfied, and the new station is shortly to be opened for the public service.

The Irish mail boats belonging to the City of Dublin Steam Packet Co. have now been equipped with wireless apparatus on the Marconi system, the first boat to leave Holyhead being the "Connaught."

The "Daily Mail" on Tuesday contained reference to some experiments with the Lepel system of wireless telegraphy of a novel character.

It is announced that the North German Lloyd has given an order for 15 of their vessels on their Eastern Asian and Australasian routes to be equipped with Telefunken wireless apparatus. Several other of the leading German lines are to be similarly equipped.

The Glasgow Chamber of Commerce will unanimously oppose the Wireless Telegraphy Bill now before Parliament on the ground that for vessels carrying 50 persons, inclusive of the crew, to be compelled to carry wireless telegraph equipments will impose a great hardship upon owners of purely cargo boats.

Wireless telegraphy is being used on a large scale in connection with the operations in different parts of the country in which the Territorial units are engaged.

The "Contractors' Record" statesthat the Chilian Government is about to instal a wireless telegraph station in the penal island of Fernandez Juan (Alexander Selkirk's island) to facilitate navigation and communication with the Continent.

COLONIAL AND FOREIGN NOTES.

Australasia.—At a recent conference of municipal representatives at *Melbourne* resolutions were carried in favour of the local tramway systems being carried on and developed as one metropolitan municipal system, and at an early date the conference is to consider the terms under which municipalities adjacent to Melbourne are to be included in the system.

The Melbourne Tramway & Omnibus Co.'s lease expires in 1916.

The "Australian Mining Standard" says at a recent public meeting at *St. Arnaud* (Victoria) a committee was formed to collect particulars concerning electricity supply and the cost of public electric lighting. Messrs. W. McLean & Co., of Melbourne, estimate that generating plant would cost about £2,000.

A recent directors' report of the *Charlton* (Victoria) Electric Light & Power Co. states that a consulting engineer is about to be appointed and a site for the power house is to be purchased.

The wages board, which has been dealing in *Sydney* with the conditions of labour of electrical workers employed by the Railways and Tramways Department and the City Council, has fixed the wages of electrical mechanics in the Railways and Tramways Department at 9s. 6d. per day, electrical fitters 11s., leading hands 12s.; electrical fitters employed by the City Council at 11s. 4d., mechanics 12s., and cable jointers—11s. 4d., with leading hands 1s. extra, and other employés 7s. 6d. to 8s. 6d. per day.

Camberwell (Victoria) Council recently decided to withhold their consent to a proposed application by Melbourne Electric Supply Co. for an order-in-council to authorise them to supply current for light and power in the whole of the municipal district.

The award of the Arbitration Court at *Perth* (W. Australia), with respect to the dispute on the city tramways, fixes the hours at 96 per fortnight for conductors and motormen, the minimum pay being 1s. per hour, and time and a quarter for overtime. Each employé is also to receive an annual holiday of seven consecutive days (including Sunday) on full pay, and an additional week without pay, if desired.

Footscray (Victoria) Gas Co. has asked the City Council to pay £2. 2s. per lamp per annum for street lighting. The average cost for the last three years has been £1. 9s. 9d., and for the last two years £1. 13s. 3d. The city surveyor regards the demand as monstrous, and Councillor Caldecott expressed the hope that it would induce the people to go in for electric lighting.

Shire Council are making inquiries as to the cost, &c., of an electric lighting scheme for *Swan Hill* (Victoria).

The *Yarrawonga* (Victoria) Shire Council are also discussing the relative merits of electric and gas lighting.

In a report to *Emu Bay* (Tasmania) Council on a proposal to adopt electric lighting in Burnie, Mr. G. H. Lofts discusses five hydro-electric schemes, but does not recommend either, on the ground of excessive cost. He recommends a local plant, and puts forward four propositions: (*a*) steam plant, capital cost £5,867, calculated to produce an annual credit balance of £275; (*b*) gas plant, cost £6,262, balance £186; (*c*) oil plant, £6,712, balance £270, and (*d*) steam locomobile set £6,312, balance £314.

At a conference of the Municipal Councils of *Coburg* and *Brunswick* (two suburbs of Melbourne) on June 25 it was resolved to convene a conference of the authorities of Brunswick, Coburg, Northcote, Preston and Broadmeadows to discuss the question of electricity supply and tramways for their districts.

Chili.—The 1909 report of Consul E. F. Hudson states that imports to the Iquique district included steel rails to the value of £1,265 (compared with £8,885 in 1908) from the U.K., £11,283 (£7,853) from Germany and £12,549 (£9,040) from Belgium; electric light machinery £45 (£217) from the U.K., nil (£1,350) from Germany and £1,125 (£7,621) from U.S.A. Other machinery £8,587 (£58,604) from the U.K., £22,997 (£30,109) from Germany, £7,847 (£5,601) from Belgium and £2,334 (£11,016) from the U.S.A.

China.—A Chinese company has been formed with a capital of $300,000 (£25,000) for lighting *Chungking* electrically. Machinery and equipment have been obtained from Europe, and a foreign engineer has been engaged in erecting it. It is expected that work will

Digitized by Google

be completed before the end of the present month. The plant will be capable of lighting 16,000 16 c.p. metallic filament lamps. A movement is on foot to instal electric lighting plant in *Chengtu*, and a company was promoted for the purpose during 1909. Plant was purchased in Europe, and supply to about 100 lamps began in February last.

Customs Decisions.—It has been decided that radium bromide and X-ray apparatus consisting of screens for cell applicators and rubber caps for applicators (either from the British Dominions or foreign countries) can be imported duty free into New Zealand.

Germany.—A report by Vice-Consul Graham (*Emden*) states that the harbour extension works which are supplied with electrical energy by a line from Wiesmoor (near Aurich) were by the beginning of 1910 connected with the same generating station by a new (reserve) cable. The use of peat in the generation of electricity in the Government works at Wiesmoor appears to have been very successful. Current is transmitted to Emden by overhead conductors. Emden has grown in importance as a landing station for the German submarine telegraph cables, &c.

The report of Consul R. Bernal on the *Stettin* district states that electricity stations have, during the last few years, been erected in Pomerania for supplying electric current to neighbouring towns, villages, estates and farms. The largest station is at Beswitz and the distributing network is over 116 miles in length; the second in size is situated at Lottin with over 83·2 miles of distributors and feeders. Two smaller stations are at Crüssow with 4·1 miles of cables, and Schmolsin with 6·8 miles. Additional stations are projected or in course of erection at Schajow, Belgard and at Anklam. These electricity works are principally controlled by associations formed by landed proprietors, and sums have been voted by the Provincial Representative Chamber to assist them. Great value has been attached to supplying small farmers and artisans living in the country with electric light and power at a cheap rate. Practical applications of electricity has lately made such progress that in the next few years the cultivation and treatment of agricultural produce will be undertaken by this means. It is already possible to plough and thresh, saw timber, clean grain, and cut turnips and beetroot by electrically-driven machines, and electricity is also extensively used in dairy farms, distilleries, factories, carpenters' shops, smithies, limestone factories, &c.

Greece.—A report by Consul MacDonell states that the electric tramway company at *Athens* have continued the electrification of their lines, only one (an alternative line between Phalerum and Piræus) being still worked by horse traction. The entire system was expected to be working this month.

Japan.—In a recent issue of the "Japan Chronicle" (Kobe) it is stated that considerable progress has been made in the arrangements for the formation of the Kinugawa Hydro-Electric Power Co. The concern was to have had a capital of 13,500,000 yen under the joint interest of British and Japanese capitalists. As, however, the British capitalists could not secure suitable terms for the concession, the Japanese promoters have decided to float the company without the help of foreign capital.

Korea.—We have received from Mr. E. Ogita, Secretary of the Imperial Japanese Residency-General in Korea, a copy of "Recent Progress in Korea," which contains a most interesting and well-written history of recent events in Korea, and particularly of the progress made by the Japanese in improving the administration and reforming the financial and industrial resources of the "Hermit Kingdom." Some useful information concerning the public undertakings, means of communication, education, &c., is also given. The work has been compiled by H.I.J.M.'s Residency-General.

Spain.—Application has been made by the Soc. Anón. los Tranvias de Barcelona for a concession for the construction and working of electric tramways in Barcelona. One line of metre gauge and another of 1·43 metre gauge.

Sweden.—Vice-Consul Amnen states that a new transformer substation of about 2,000 H.P. has been erected in *Hudiksvaal* for supplying power transmitted from the Arbra Elektricitetsverk (about 33 miles distant) to several factories in the town and neighbourhood and also for lighting.

At Forssan (about 9 miles from Hudiksvall), a new wood-pulp mill and a cardboard factory are both now run by electric power from Arbra.

To facilitate discharging (and transport) of coal and chemicals from Stocka to the sulphite mill at Ström (about 15 miles from Hudiksvall) an electric derrick crane has been erected at Stocka and an electric railway built between these places.

Vice-Consul Carrick (at *Gefle*) says the Stora Kopparbergs Bergslags Aktiebolag of Harnäs is completing a large power station at the Buller Waterfall, near their ironworks at Domnarfvet. The company expects to obtain about 24,000 H.P. to be used partly for the driving of the large paper mill at Qvarnsveden and partly for the generation of electricity for smelting steel at Domnarfvet. The electric smelting furnace is said to be technically and commercially successful.

Sydney (N.S.W.)—The report of the city electrical engineer (Mr. H. R. Forbes Mackay) on the City Council's electricity supply undertaking for 1909, states that capital expenditure was £534,280 (compared with £435,105 at Jan. 1, 1909).

Revenue was £118,275, working expenses £52,976 (plus £14,362 payments to purchased companies). Depreciation at 3 per cent. and sinking fund 1 per cent. required £19,273, leaving £46,026 profit, before deducting amounts paid to purchased companies. The maximum load was 6,040 kw. (compared with 4,300 kw. in 1908), and the load factor 31·11 (14). There were 2,945 (2,219) customers, and motors connected were 10,978 H.P. (8,290 H.P.) Units sold were 11,914,720 (8,673,942). Average revenue per unit sold was 1·132d. (1·38d.).

Turkey.—A report on the trade of Constantinople and district for 1909 states that an electric tramway system is occupying the attention of the local authority at Adana.

The town of Tarsus, though formerly larger than either Adana or Mersina, has lost ground somewhat. Quite recently, however, electricity generating plant driven by water turbines has been established, and the streets are now lighted electrically. Electric power will shortly be used in the spinning factory at Tarsus, and there is a private scheme under consideration for transmitting electric power from Tarsus to Mersina.

At Beirut the gas company has obtained an electric lighting concession and imported machinery from Europe. It was expected the works would be in operation by about now.

United States.—A report by Consul-General Nugent states that the value of *Chicago* manufactures in 1909 was £367,282,280 (compared with £319,723,472 in 1908), including electric supplies £8,796,200 (campared with £7,828,000), machinery £7,004,000 (£5,871,000), boilers £1,161,840 (£968,200), cars, bridges, lifts, &c., £8,219,400 (£7,148,200).

During 1909 the Illinois Steel Co. installed the first Héroult electric furnace of large capacity at S. Chicago, Ill., that has been built in the United States. The furnace has been producing electrically refined steel at the rate of about 3,000 tons per month, and experimental lots of rails made under the process have been supplied to some of the Western railroads. The cost of electrically refined steel is stated to be higher than that of steel made by the ordinary processes.

Vice-Consul Meredith (*Detroit*) says the tunnel under the Detroit river between the U.S.A. and Canada is practically completed, and the third rail system of electric traction will be used in the tunnel. Bench walls in the tunnel carry a large number of ducts for power, telephone, telegraph and electric light cables.

Exports from *Boston* to the United Kingdom in 1909 included electrical appliances £20,632 (against £19,891 in 1908), electrical machinery £49,868 (£21,793), engines £239 (£747), and boilers and parts of engines £7,142 (£10,916).

Consul-General Hearn (*San Francisco*) says electric power is used extensively in California, the consumption in that State being 555,177 kw. for 1909, against 163,904 kw. for Washington, the next highest of the western districts.

Vice-Consul Mortimer, reporting on the trade, &c., of *Los Angeles*, (Cal.), says all the tramways in this city are worked by electricity. There are five systems with 275 miles of track in the city. The Pacific Electric Railway Co. are working tramways in the city and vicinity on 559 miles of track. The Los Angeles Pacific Co. have 175 miles working. These tramways connect Los Angeles with the surrounding towns, using the streets and country roads, and in some instances private rights of way. The tracks are well laid and the cars run at a high rate of speed—about 45 miles an hour. The electric supply companies supplied 245,797,449 units of current for lighting and power in 1909. In San Francisco alone there is a delivery of electric energy amounting to 275,000 H.P., and in Los Angeles 135,000 H.P. On the electric railways in California there are 2,516 cars, while the number of miles of standard gauge electric track is 1,653. The electric power generated by steam plants is more than equal to that generated by water power in the State. The increase of electric power plants throughout the State has had a marked effect in the mining regions. The numerous mountain streams furnish the original source of power, and this is distributed by electricity throughout the mining districts. This has had the effect of materially cheapening mining operations and has rendered possible the working of mines which were formerly idle. The electric iron smelter on the Pitt river (Shasta County, Cal.) has proved a success, and in August, 1909, was producing pig iron at the rate of 25 tons per day without the use of any blast or coke. The iron was delivered to a foundry at Redding at $25 (£5. 4s. 2d.) a ton, or less than the ordinary price at tidewater. It is pronounced to be of the finest quality for casting purposes.

Venezuela.—The report of Vice-Consul H. Tom on the trade of the *Caracas* district for 1908-9 states that the tramways of Caracas are owned by the United Electric Tramways Co. of Caracas (Ltd.), of London, but a local company (the Compañia Anónima Tranvias Eléctricos de Caracas) was formed to meet the requirements of Venezuelan law. The company's concession is for 99 years, and the service was opened March 15, 1908. There are about 15 miles of

Digitized by Google

single track of 3 ft. 6 in. gauge, with crossings. There are 41 cars and on an average about 300,000 passengers a month are carried. The power, generated by water power about 10 miles from the city, is taken from a local company. The company has a reserve plant of three Diesel engine sets of 240 H.P. each, and a storage battery capable of carrying the entire load for one hour. The local electric power company is now erecting a new generating station, and the fall of the same river will be utilised to run the new station.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Barnes.—The capital expended on the electricity undertaking at March 31 was £65,201, an increase of £1,586 during the year.

The annual revenue was £10,921, including £8,382 from the sale of current for private lighting and power, and £1,968 from public lighting. Expenses were £4,052, leaving a gross profit of £6,869. Interest came to £1,964 and instalments of principal to £2,446. £1,451 was placed to reserve, and £716 devoted to meeting expenses of executing the order which are not chargeable to capital. £5,300 was carried forward, against £4,980 in 1908-9. 1,024,131 units were generated, 232,607 units were supplied to public lamps (266½ amperes Nernsts and 231 metal filaments), and 692,693 sold to private consumers. The total maximum supply demanded was 505 kw.

Beckenham.—The accounts of the electricity department for the year ended March 31 show a net deficit of £131.

The chairman of the Electricity committee (Mr. SJOLLEMA), in moving the adoption of the accounts at the last meeting of the Council, said that the most satisfactory feature was the important reduction in generation expenses, a reduction compared with the previous year of no less than £2,214. 0s. 3d., of which coal was responsible for £2,056. 3s. 9d. After making provision for interest and sinking fund charges the accounts showed an improvement over the previous year of £1,168. 2s. 10d., not sufficient, however, to ensure a profit because of savings effected by consumers, who had actually paid £536. 19s. 5d. less for current, although 184 more had been supplied. The revenue from tramway current was up by £112. They had appointed two canvassers and had opened showrooms in order to push the sale of electricity. They could supply 500 more customers without increase of plant.

Darwen.—The accounts of the tramways department for the year to March last show capital expenditure £85,609, amount borrowed £86,100, redeemed £21,100.

Total revenue was £13,723, working expenses (less depreciation) £8,825, depreciation £1,050, and capital charges £4,308, the net deficit being £658. Passengers carried were 2,562,218, car miles run 246,501, and units used 422,805 (1·71 per car mile). Total revenue was 13·36d. and working expenses (including power cost and depreciation) were 9·61d. per car mile.

Eccles.—The income of the electricity department for the year ended March 31 was £9,682, including £9,016 from the sale of electrical energy for private and public lighting and traction.

Total expenses were £5,286, and the gross profit £4,397. Interest absorbed £1,353, sinking fund contribution and repayment of loan (£1,681), other charges £145, leaving a balance of £1,218 which has been transferred to capital account for expenditure in excess of L.G. Board sanction. The gross capital outlay is £51,241, an increase of £2,040. £9,361 has been paid off. 309,575 units were sold to private consumers, 764,778 units supplied to the tramways department and 88,754 for public lighting.

Greenock.—The profit on the past year's working of the electricity undertaking was £3,250, which is a higher figure than in any previous year.

Halifax.—The total revenue of the tramways department for the past year was £89,270, against £86,157 in the previous year.

After deducting working expenses, interest, sinking fund and other charges, the net profit was £13,065, compared with a net loss of £13,542 in 1908-9, and of £9,605 in 1907-8. The route mileage of the tramways worked by the Corporation is now 37 miles 697 yds. The receipts from parcels have increased to £1,803. 5s., against £1,528. 15s. 8d.

Ilford.—The capital expended on the electricity department at March 31 was £181,326, the same as in 1909.

Total revenue was £29,747 (against £28,721), including £16,773 for current sold for private lighting and power, £7,305 for public lighting, and £4,577 from the tramways. Working expenses were £16,806 and £75 was carried forward to provide for irrecoverables, leaving a gross profit of £12,866 (7·42 per cent. on capital), against £10,679 (6·57 per cent.) Interest came to £5,754 (against £5,676), and repayment of debt charges £5,543 (against £5,002), leaving net profit £1,569, against £1 in 1908-9. The number of units sold for private supply was 1,553,133 (against 1,433,711), for traction 976,513 (against 1,020,960), and for public lighting 622,945 (against 780,405), a total of 3,152,591 (against 3,235,076). The average price per unit sold was 2d. against 1·87d. There were 3,545 consumers, an increase of 243. The maximum load was 1,665 kw. (against 1,675 kw.), and the load factor 21·61 against 22·05 per cent. The total costs were 1·03d. per unit (against 1·11d.), but coal showed a decrease of 0·14d. (0·48d. against 0·62d.) There are 106 arc and 1,570 incandescent lamps for public lighting.

Norwich.—The income of the electricity department for the year ended March 31 was £37,632 (including £35,876 for sale of current), increase £443.

The expenses were £16,524, compared with £19,070, leaving a gross profit of £21,109 to meet interest and sinking fund (£15,146), so that the net profit was £5,963. After crediting £126 from 1906, placing £2,000 to depreciation account, and devoting £360 to purchase of Duke-street property, £3,728 was carried forward. On the wiring account there was a profit of £271, but depreciation has only been calculated on a 20 years' basis. The outlay on free wiring during the year was £1,472, making the total £12,444. Units sold for private lighting were 2,008,167, an increase of 154,259 over 1908-9, for public lighting 42,598 units (increase 731), and for power 2,062,432 units (decrease 108,662). The total works costs were 0·943d. per unit against 1·062d.

Perth.—It was reported to the City Council on Monday that the revenue of the electricity department for the past year was £7,935. After meeting expenses, and paying interest, transferring £1,037 to sinking fund, and putting £475 to reserve, there was a balance to be carried forward of £67.

The receipts of the tramways department were £8,516, and the expenses £5,362, leaving £3,153 to meet interest and sinking fund charges (£3,166). In addition, the interest and instalment on purchase price required £1,157, and the net deficit on the year's working was consequently £1,470.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published

TENDERS INVITED.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms, &c., may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

LONDON County Council invite tenders for the covering with asbestos tape of certain electric cables in manholes in the south of London. Specification, drawing, form of tender, &c., from the Clerk of the Council, Spring Gardens, S.W. Tenders by 11 a.m. Aug. 30.

LONDON County Council also invite tenders for wiring and fitting for electric lighting of the second section of the central car repair depot, Woolwich-road. Specifications, &c., from the Clerk of the Council. Tenders by 11 a.m. Tuesday, Aug. 30.

Digitized by Google

NEWPORT (Mon.) Electricity and Tramways committee invite tenders for supply of carbon filament electric lamps, radiator lamps (British made), flame arc lamp carbons for Excello and Oliver type lamps, and a.-c. and d.-c. two-rate and prepayment meters, during the ensuing 12 months. Specification and schedule from the borough electrical engineer and tramway manager, Mr. H. Collings Bishop, M.I.E.E. Tenders to the Town Clerk, Town Hall, Newport, Mon., by first post Aug. 15.

OLDHAM Surveyor's and Tramways committee require tenders by Aug. 17 for materials and labour (except electrical equipment) required in construction of a tramway. Forms, &c., from the Borough Surveyor.

CHELMSFORD Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

SALFORD Tramways Committee want tenders by 10 a.m. Aug. 15 for supply of 500 tons of steel tramway rails. Specification, &c., from general manager.

BOURNEMOUTH Tramways committee want tenders by Aug. 31 for reconstruction of 2½ miles of tramway permanent way and supply of 450 tons of rails, with fastenings. Specifications, &c., from the General Manager.

Tenders are wanted by 5 p.m. Aug. 25 for supply of telephone apparatus and cable (main central battery system and metallic circuit telephone switchboards, &c.) for the Lancashire County Asylum, RAINHILL. Specification, &c., from the Clerk.

SOUTH DUBLIN Guardians want tenders by noon Aug. 24 for wiring and fitting the workhouse for electric lighting. Specifications, &c., from the Clerk on payment of £1. 1s.

ROCHDALE Electricity committee want tenders by noon, Aug. 31 for 12 months' supply of paper insulated cables. Specification from the engineer and manager.

HACKNEY (London) Council want tenders by 7 p.m. Sept. 15 for extension of main switchboard. Specification, &c., from the Town Clerk.

KETTERING Council require tenders by noon Aug. 22 for the supply and fixing of three steel chain independent coal elevators. Specification, &c., from the Electrical Engineer.

SKIPTON Council require tenders by Aug. 17 for supply of a gas engine and dynamo and for the wiring, &c., for electric lighting at the Town Hall.

POPLAR (London) Guardians want tenders by 6:30 p.m. Aug. 31 for 12 months' electrical supplies, ironmongery, packing and jointing, &c. Forms, &c., from the Clerk.

IPSWICH Corporation want tenders by Aug. 22 for one year's supply of underground cables. Specification from the Chief Engineer.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

Tenders are invited for supply to the Corporation of the City of MELBOURNE of 4,840 yds. single conductor lead-covered cable, suitable for use on a circuit having a working pressure of 460 volts, and 880 yds. concentric lead-covered cable for use on a circuit having a working pressure of 2,000 volts. Specifications, forms and conditions from Messrs. McIlwraith, McEacharn & Co. Proprietary (Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by noon Tuesday, Aug. 23.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE, will receive tenders until noon Sept. 7 for supply of glass cells, corks and tubes and porous cups for batteries, battery material, chemicals, &c. Specifications, &c., from the High Commissioner for the Australian Commonwealth, London. Local representation is necessary.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. Aug. 30 for supply of electrical sundries, insulators, wire and sulphate of magnesia. Local representation necessary. Further particulars from 72, Victoria-street, London, S.W.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

The Burgemeester en Wethouders van AMSTERDAM announce that on Aug. 22, 1910, the Corporation will receive tenders for delivery and erection of a 6,000 kw. steam turbo-generator unit for the Corporation electricity works. Specification (in German), price Fl.2.50, and further particulars from the Gemeente-Electriciteitswerken, Hoogte Kadyk 200, Amsterdam, Holland.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Italian State Railways Administration, 16, Via Ludovici, ROME, want tenders by Aug. 22 for supply of 584,000 common carbons for arc lamps. Only firms on list kept by administration are generally allowed to tender. Local representation is practically necessary.

Tenders will be received at the offices of the municipality, Gorodskaia Uprava, ST. PETERSBURG, up to 11 a.m. Aug. 2/15 for supply and installation of switchboards for the extension of the St. Petersburg telephone system. Particulars from the telephone station, Morskaia 22, St. Petersburg.

MOSTAR (Austria-Hungary) municipality will receive tenders until Oct. 1 for the installation of electric generating plant.

TENDERS RECEIVED AND ACCEPTED.

Manchester Council have accepted the tender of the Union Cable Co. for service cables at £1,500.

The chairman of the Electricity committee (Mr. Howarth) explained to the Council that the lowest British tender was £2,750. The Union Co. proposed to erect works in Essex.

An amendment to refer the matter back in order to consider the question of accepting a British tender was rejected.

Stockport Council have accepted the following tenders for annual supplies:—

Morgan Crucible Co., carbon brushes; British Insulated & Helsby Cables, overhead line materials; T. Richardson, rubber blocks; H. Hollingdrake & Son, bolts, nuts, &c.; McClure & Whitfield, two commutators for motors.

Sheffield Council have accepted the following tenders:—

British Insulated & Helsby Cables, 2 miles of figure 8 bronze trolley wire 8½d. per pound (less 2¾ per cent.); W. T. Glover & Co., 10 tons of h.c. copper wire to be made up into cables during two years; Gilbert Heathcote & Co., constructional steelwork for extensions to boiler house at Neepsend station, £6,355. 3s. 7d.

Salford Council have accepted the following tenders:—

Lightfoot Bros., telephonic installation at Sanatorium, £27. 10s.; British United Road Traction Co., 28-34 H.P. Halley petrol power wagon, £670; T. Robinson & Son, moulding machine, £66. 1s. 8d., and grinding machine, £19. 10s.; C. Churchill & Co., lathe, £58; Selsor Engineering Co., shaping machine, £68.

Walsall Council have accepted the tender of H. G. Richardson & Co., for l.t. switchboard and altering a switchboard at £88. 10s., and that of the Union Electric Co., for three h.t. isolation switches at £19. 10s.

Warrington Council has accepted the tender of George Wallington for concrete foundations for the turbo-alternator and condensing plant, and the erection of a building for switchboard extensions at £300.

Sydney City Council are recommended to accept the tenders of the Australian General Electric Co. for the supply of switchboards and transformers, and Noyes Bros., British Insulated & Helsby Cables and Jas. Connolly for other electric lighting materials.

Motherwell Council have accepted the following tenders:—

Chamberlain & Hookham, meters; Balcke & Co., cooling tower, £818; Callender's Cable & Construction Co., cable, £530; Siemens Bros. Dynamo Works, switchboard extension, £305.

Belfast Harbour Commissioners have accepted the tenders of Siemens Bros. Dynamo Works for a dynamo, and that of Jas. Howden & Co. for a steam engine to be direct coupled to the dynamo.

Digitized by Google

Folkestone Council has accepted the tender of E. Morgan at £69. 15s. for supply and fixing electric fittings at the Corporation offices.

Ashstead Council have accepted the tender of the Leatherhead & District Electricity Co. for lighting 54 public lamps at £2. 17s. 6d. each per annum.

Stretford Council have accepted the tender of the Tudor Accumulator Co. for alterations to and extensions of the existing storage battery at £784. 9s.

Leith Corporation have accepted the tender of the British Westinghouse Co. for a 500 kw. mixed pressure turbine and d.c. generator, condensing plant and cooling tower at £4,775.

Fareham Asylums Committee of Southampton County Council have accepted the tender of Shalders & Davis, for electrical machinery at £1,715.

Eccles Council have accepted the tender of E. M. Evans & Sons for wiring the new secondary school at £460.

Torquay Council has placed an order with Ferranti Limited for the annual supply of meters.

The contract for the electric lighting of the new Hamilton Academy has been secured by Wm. Torrance at £1,500.

Bury (Lancs.) Council have accepted the tender of Siemens Bros. & Co. for the supply of e.h.t. trunk mains.

Folkestone Council have accepted the tender of E. Morgan for electric fittings at £69 for the municipal offices.

Electric Lift Contracts.—A. W. Penrose & Co. have secured the contract for the electric lifts required in the new head post office, Edinburgh, the contract amounting in all to about £4,000. The firm have also other work in hand for the P.O. authorities, including three 30 cwt. goods lifts for the new western district post office, three a.c. lifts for Sheffield, one passenger lift for Leeds, and one passenger lift for Newcastle-on-Tyne.

BUSINESS NOTICES.

Messrs. J. Parkinson & Co., Post Office Chambers, St. Nicholas-street, Newcastle-on-Tyne, have been appointed by Messrs. Tetley & Co. their sole agents for Newcastle and district.

Mr. Alf. E. Croager, Norfolk House, Laurence Pountney-hill, London, E.C., has been appointed London representative to Messrs. Joseph Williamson & Co., screwing machine makers, of Manchester, for all sizes from $\frac{1}{8}$ in. to 36 in. diameter.

The works of the Telegraph Condenser Co. (Ltd.) have been removed to Vauxhall-street, Kennington Oval, S.E.

Mr. P. P. Kipping has removed from 71, Queen Victoria-street, to Midland Bank Chambers, Queen Victoria-street, E.C. Telegrams, "Peelcontel London." Telephone, London Wall 673.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, on Thursday, 25th inst., at 11 a.m., unserviceable and obsolete stores, including quantities of iron and steel, brass, copper, gunmetal, lead and antimony alloy, zinc, mixed metal and turnings, &c., dynamo, drums of cable, lathes and other machine tools, telegraph and electric light fittings and instruments, electric lamp bases, &c. The lots may be viewed at the Royal Arsenal, Woolwich, on Monday, Tuesday and Wednesday, previous to and on morning of sale. Catalogues from the War Office, Whitehall; the Ordnance Office, Tower; and the Ordnance Office, Royal Arsenal, Woolwich See also an advertisement.

Patents Development.—The proprietor of letters patent No. 28,542/1907, relating to "Electrical induction furnaces," desires to enter into arrangements for exploiting same. Communications to Messrs. J. E. Evans-Jackson & Co., 19 and 20, Holborn Viaduct, London, E.C.

The proprietor of patent No. 23,491/1902, relating to "Magneti. wheels" desires to dispose of same, or to grant licences for working in this country. Applications to Messrs. Cruikshank & Fairweather (Ltd.), 65 and 66, Chancery-lane, London, W.C.

Electric Clocks.—Electric time service is making rapid strides. The Synchronome Co. inform us that they are installing their system of electrical impuls dials in a number of public buildings, works and factories, &c.

Conduit and Conduit Accessories.—The General Electric Co. announce that they will shortly be issuing a new catalogue for conduit and conduit accessories, pending the publication of which all former list prices and quotations are withdrawn as and from July 21. In the meanwhile the company will supply customers with net quotations for anything they may require.

National Telephone Directories.—The new edition (July, 1910) of the National Telephone Co.'s directories for the United Kindgom

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included

have just been issued. The two volumes into which the complete directory is divided continue to increase in bulk, indicating a steady growth in the number of subscribers to the company's system. There is nowadays no business house of importance without telephone facilities. Vol. I. contains sections 1 to 26 of the directory, and comprises the important London area, and the Midland, Southern and Western Provinces; Vol. II. includes sections 27 to 55 and embraces Scotland, the North-Western and Northern Provinces and Ireland. The published price of the set is 30s., or 15s. each volume. The directories can also be obtained in the smaller sections. The London directory can be obtained price 2s.; the Midland Provinces Sections (2 to 9 inclusive) complete 5s., or 1s. each separate section. As a rule, each of the sections can be obtained for 1s. each, but the price of some 16 of the smaller provincial sections is only 6d. each.

Touring in Bucks.—The Great Central Railway Co. has prepared a convenient pocket guide book which gives illustrated details of a number of cycling tours in Buckinghamshire. By taking the Great Central to certain stations the cyclist can find his way through the most picturesque byways and reach some other point on the railway from which to return to town. The most intricate turnings on the various routes are indicated by photographs, and these, in conjunction with the letterpress, make it impossible to lose one's way. The booklet is interspersed with interesting notes of the principal places en route. Copies can be obtained, post free 3d., from the Great Central Railway Publicity Dept., 216, Marylebone-road, London, N.W.

CATALOGUES, &c.

"Butt" Arc Lamp.—We have received from the General Electric Co. an advance copy of a pamphlet they are issuing dealing with a new flame arc lamp shortly to be placed on the market. It is suitable for both direct and alternating current, and is self regulating. There is no clockwork and no shunt coils. It can be run on alternating current of 25 cycles per second. It is made in three types: short hour, having a life of 8–10 hours, long hour 16–18 hours, and the double carbon lamp 32–38 hours.

G.E.C. Switchgear.—The General Electric Co. have also sent us a couple of pamphlets dealing with iron clad switchgear of the Salford type, and Witton switches. The latter of these was described in the last issue of The Electrician, while with regard to the former it may be said that they are all good standard patterns with cases and designs suitably protecting the switches from dust and damp. A pamphlet describing this firm's well-known Flamgold arc lamps has also come to hand.

"Tricity" Cookers.—We have received from the Berry Construction Co. an illustrated catalogue showing the latest type of their well-known "Tricity" cookers. These can be provided with extensions so that from small beginnings a large and efficient cooking apparatus can easily be built up.

Clyde Capstans.—A pamphlet from Messrs. Bruce Peebles & Co. describes in detail the operation of the Clyde patent electric capstan.

Litholite Insulators.—Litholite (Ltd.) send us a number of sheets giving sectional drawings and details and dimensions of the insulating equipment made by them.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during June, 1910, and (*b*) during the current year from Jan. 1 to July 31, with the increases or decreases compared with the corresponding periods of 1909:—

Electrical machinery (*a*) £43,712 (decrease £13,448), (*b*) £323,144 (increase £33,217); telegraph and telephone cables (*a*) £7,250 (decrease £3,086), (*b*) £79,697 (increase £6,886); telegraph and telephone apparatus (*a*) £10,504 (decrease £1,682), (*b*) £99,606 (decrease £5,435); other electrical wires and cables, rubber insulated (*a*) £21,080 (decrease £2,632), (*b*) £120,395 (increase £67,647), with other insulations (*a*) £2,785 (increase £1,969), (*b*) £47,360 (decrease £37,264); carbons (*a*) £10,183 (decrease £1,073), (*b*) £78,216 (increase £1,383); glow lamps (*a*) £51,162 (increase £20,263), (*b*) £320,727 (increase £72,590); arc lamps and electric searchlights (*a*) £224 (increase £160), (*b*) £2,025 (decrease £6,865); parts of arc lamps and searchlights (other than carbons) £4,549 (decrease £1,063), (*b*) £40,192 (increase £6,853); primary and secondary batteries (*a*) £3,368 (increase £815), (*b*) £23,939 (decrease £3,147). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £120,264 (increase £16,237), (*b*) £841,091 (increase £102,526).

Digitized by Google

Exports.—The exports of electrical machinery, material, &c., (*a*) during July, 1910, and (*b*) during the current year from Jan. 1 to July 31, and the increases and decreases compared with the corresponding periods of 1909, are as follows :—

Electrical machinery (*a*) £172,252 (increase £49,689), (*b*) £891,675 (increase £61,451); telegraph and telephone cables (*a*) £129,999 (increase £106,446), (*b*) £1,030,093 (increase £595,220); telegraph and telephone apparatus (*a*) £18,167 (decrease £31,783), (*b*) £100,134 (decrease £73,310); other electrical wires and cables, rubber insulated (*a*) £28,960 (increase £6,312), (*b*) £228,323 (increase £78,898), with other insulations (*a*) £25,450 (decrease £2,234), (*b*) £169,946 (decrease £5,377); carbons (*a*) £1,199 (increase £211), (*b*) £9,861 (increase £4,673); glow lamps (*a*) £9,548 (increase £3,802), (*b*) £72,365 (increase £31,399); arc lamps and searchlights (*a*) £1,602 (decrease £764), (*b*) £11,022 (decrease £889); parts of arc lamps and searchlights (other than carbons) (*a*) £1,293 (increase £790), (*b*) £8,032 (decrease £921); primary and secondary batteries (*a*) £16,870 (increase £7,314), (*b*) £70,036 (increase £3,982). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £269,895 (decrease £118,905), (*b*) £1,962,689 (increase £688,253).

LIQUIDATIONS.

A summary of the liquidator's accounts in the matter of the Phosphor Bronze Co. (Ltd.) has been issued, covering the period from Dec. 14, 1909, to June 14, 1910. The whole of the creditors have been paid in full, the debentures have been paid off (or amount provided for same), and there is a balance of £12,697. 16s. 3d. to the credit of the company.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

April 30, 1910.

10,693 KOOPMAN & PONTELEC WELDING PATENTS. Supports for electric conductors.*
10,694 KOOPMAN & PONTELEC WELDING PATENTS. Electric heating machines.*
10,705 BROWN, GOURLAY & GOURLAY. Electric conduit threaders.*
10,706 GODFREE. Electro-mechanical separator. (Date applied for, 28/5/09.)*†

May 2, 1910.

10,717 HARRIS. Safety recessive shell for detonation for blasting purposes when fired by electric current. (Addition to No. 225/09.)
10,718 HALL. Electric ignition apparatus.
10,728 TAYLOR. Instantaneous switches for alternating and direct-current circuits.
10,745 HURD. Telegraphic slip winder.
10,748 LIDDLE. Motor-driven capstans.
10,749 LANCASHIRE DYNAMO & MOTOR CO. & MASON. Electrically operating planing machines and the like reciprocating tools.
10,771 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Circuit breakers.*
10,772 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Electric circuit controllers.*
10,773 SIEMENS BROS. DYNAMO WORKS. BATE & GLADDY. Electric lamp holders.
10,774 BALDWIN. Sound-reproducing devices of the telephone-receiver type.
10,788 LANZAROTTI & CRESFI. Systems of telegraphy from trains and the like.
10,799 RANSCH. Temporarily short closing of electrical currents.*
10,817 FESSENDEN. Wireless signalling. (Date applied for, 19/7/09.)*†
10,820 ZAHRINGER. Device for operating magneto-electric ignition machines.*
10,829 B.T.-H. Co. (G.E. Co., U.S.) Electric conductors of refractory metal.*

May 3, 1910.

10,842 CHRISTMAS. Duplicated reversing sparking plugs.
10,843 MORSE. Power-transmission mechanism. (Date applied for, 15/12/08. Comprised in No. 28,923, dated 10/12/09.)*
10,945 NICHOLLS. Attachment to telephones to note telephonic communications.
10,869, 10,871, 10,873 and 10,874 HARRISON. Manufacture of filaments for incandescent electric lamps.
10,870 and 10,872 HARRISON. Exhaustion of incandescent electric lamps.
10,913 SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke G.m.b.H., Germany.) Regulation of the power factor in the external circuit of polyphase electric machines.*
10,917 FRANTZEN. Electric furnaces. (Date applied for, 5/5/09.)*†
10,919 COX. Electrical switches.
10,932 WEEKES. Combined installations for power generation and industrial heating.
10,943 & 10,955 LAKE. (William Edward Clark, U.S.) Arc lamps.*
10,961 PARTINGTON. Multiple fusible cut-out for electrical circuits.*
10,964 & 10,965 GRAHAM. Telephonic systems and apparatus.*
10,970 ZWEIGBERGK. Dynamo-electric machines.
10,972 HAZLEHURST & LONGSTRETH'S. Automatically breaking the charging circuit of a secondary battery.

May 4, 1910.

11,013 MURRAY. Heating interiors by means of electric radiators.
11,021 FISH & PARKER. Shade-holders for electric lamps.
11,024 AKT.-GES. BROWN, BOVERI ET CIE. Driving dynamo-electric machinery. (Date applied for, 5/5/09.)*†
11,031 DUNNITHORNE. Production, control and application of currents of electricity which vary periodically in intensity.
11,048 BOULT. (International Telechronometer Co., U.S.) Telephone apparatus.*
11,051 LOBEL & BRITISH EVER READY ELECTRICAL CO. Holders or fittings for electric incandescent lamps.*
11,054 SIEMENS SCHUCKERT WERKE G.M.B.H. Searchlight apparatus. (Date applied for, 10/5/09.)*†
11,072 PEFLOW, HEYN & LEYLAND. Electric signalling lamps carried on bicycles and the like.
11,085 BROWN. Telephone relays or transmitters.

May 5, 1910.

11,105 GUNNER. Earthing device for electrical conduits.
11,107 KRAUSE. Manufacture of electric metal filament lamps. (Date applied for, 6/5/09.)*†
11,137 MITCHELL. Holders for electric glow-lamps.
11,145 FLURY. Operating electric switches and the like.
11,146 FENNER. Arc lamps.
11,154 & 11,155. FESSENDEN. Wireless signalling. (Date applied for, 29/1/10.)*†
11,157 MUNR & RAILLESS ELECTRIC TRACTION CO. Trolley-poles for electric traction systems.
11,175 SEWARD, KUGELGEN & BIDDER. Electrolytic production of light metals and particularly sodium. (Date applied for, 10/5/09.)*†
11,184 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Motor controllers and like electric switches.*
11,186 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Starting devices for electric motors.*
11,188 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Electromotor-controllers and like electric switch.*

May 6, 1910.

11,251 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges., Germany.) Telephone exchange circuits.
11,260 THORNTON. (John Tefft Clarke, U.S.) Circuit closers.*
11,275 BAKER & LONGSTRETH'S. Electric couplings.
11,277 EVERSHED & VIGNOLES, EVERSHED & PAYNE. Binding screws or terminals for electrical purposes.*
11,281 MCKENZIE & HOLLAND & WOOD. Electric contact makers.*

May 7, 1910.

11,294 GOLDSCHMIDT. Production of high frequency currents for use in wireless telegraphy and telephony.*
11,333 HOWARD & COAD. Telephone mouthpieces.*
11,356 GARCIN. Dynamo-electric machines. (Date applied for, 8/5/09.)*†
11,359 MARCONI'S WIRELESS TELEGRAPH CO. & PRINCE. Portable apparatus for wireless telegraphy.
11,360 MARCONI'S WIRELESS TELEGRAPH CO., BANGAY & PRINCE. Carrying portable motors and dynamos on horseback.

May 9, 1910.

11,385 CROSSLEY & HAMER. Cord grips for incandescent lamp-holders.
11,415 KITSEE. Metallic filaments for electric lamps.*
11,429 YOUNG. Starting and controlling electric motors.
11,437 DAALEN. Actuation of controllers for electric machinery. (Addition to No. 15,203/09.)*
11,439 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Controlling electric motors.*
11,494 REID. Electric clocks.

May 10, 1910.

11,559 WALTERS. Stage arc lamps.
11,564 PEARSON. Electric switches.
11,569 CHADWICK & CLARKE. Detachable power handle for use on electrical controllers on tramcars, motor cars, trains and the like.
11,581, 11,582 and 11,583. HEIMANN & SCHAFFER. Working arc lamps in series with incandescent lamps. Addition to No. 747/10. (Date applied for, 2/8/09, 10/10/09, 10/1/10.)*
11,600 BOSCH. Terminals for electric cables. (Date applied for 23/7/09.)*†
11,602 FESSENDEN. Telephone transmitters and relays.
11,614 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Alternating-current magnets.*
11,626 GRAHAM. Telephonic apparatus.*

May 11, 1910.

11,644 FAHN. Electric lighting of motor vehicles.
11,658 ATKINSON. Guiding apparatus for electric trolley wheels for tramways and the like.
11,671 IRWIN. Selective signalling.
11,707 B.T.-H. Co. & WEDMORE. Electric switch mechanism.
11,708 B.T.-H. Co. (G.E. Co., U.S.) Electric switches.
11,716 THOMSON. Electric furnaces. (Date applied for 13/5/09.)*†
11,717 THOMSON & FITZGERALD. Electric furnaces. (Date applied for, 13/5/09.)*†
11,718 FITZGERALD. Electric furnaces. (Date applied for, 13/5/09.)*†

May 12, 1910.

11,746 KERNAN. Electric lamp or like switches.
11,756 LACY. Electrical circuit breakers, fuse bridges, cut-outs, distribution boards and the like.
11,781 STERN. Electrical accumulators. (Date applied for, 12/5/09.)*†
11,792 BEAVER, SWENDOWER, PREECE & CLAREMONT. Electric cable.
11,812 MACBRAYNE. Power transmission plants.
11,830 ZWEIGBERGK. Controllers for dynamo-electric machines.*
11,837 ESTELLE. Depolarising agents for electric batteries. (Date applied for, 13/5/09.)*†

May 13, 1910.

11,854 AIKEN. Controlling electric lights and apparatus therefor.
11,885 CLARK. (Brown Spin-Wright Co., U.S.) Power transmission apparatus.
11,896 SIEMENS BROS. DYNAMO WORKS & PICKERING. Armature windings of dynamo-electric machines.*
11,903 FESSENDEN. Signalling by electromagnetic waves. (Date applied for, 18/5/09.)*†

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

6,758 DURTNALL. Electrical transmission of power and speed regulation.
10,680 KILROY & EVERSHED & VIGNOLES. Starting of electric motors.
10,757 ELICSON. Electric Switches.
10,860 MARTYN. Junction boxes for electric wires and cables.
11,172 B.T.-H. Co. (G.E.Co., U.S.) Electric heating devices.
11,242 SHARMAN. Master switches for radio-telegraph and radio-telephone stations.
11,282 GROTE. Arc lamps.
11,285 B.T.-H. Co. & WEDMORE. Electric distribution systems. (Cognate application, 12,048/09.)
11,295 LEAKE. Electrical transmission of signals and the like.
11,302 and 11,303 VON ZWEIGBERKG. Electric controllers.
11,304 VON ZWEIGBERGK. Protection of high-tension direct-current motors in series.
11,402 GODDARD. Prepayment electricity meters.
11,445 DAWSON & PYNE. Control of electric motors.
11,482 DAVY. Arc lamps.
11,539 B.T.-H. Co. (G.E. Co., U.S.) Rectifying apparatus for electric currents.
11,540 LAURIE-WALKER & NIBLETT. Ploughs for electric tramcars.
11,843 COWPER-COLES. Compound anode and cathode bars.
11,981 PEASE. Flexible protection for electric cables and the like purposes. (Cognate application, 25,920/09.)
12,005 NICHOLSON & HIGHAM. Forming and transforming cipher messages for telegraphic and other purposes.
12,139 IRELAND. Controlling and indicating the condition of control of electrically propelled tramcars and other vehicles.
12,146 VERNIER. Electrical conductors.
12,395 ELECTRIC CONTROL, MACMILLAN & DRYER. Electric switch-operating mechanism.
12,607 SMITH & WATSON. Trolley-heads for electrical tramcars.
12,677 BENKÖ. Carbon electrodes for galvanic elements.
12,689 B.T.-H. Co. & HOLDEN. Electric meters.
13,831 ABRAHAM & BRITISH PNEUMATIC RAILWAY SIGNAL CO. Electric relays for railway signalling and other apparatus.
14,674 WEAVER. Controlling arc lamp carbons.
14,790 PEARSON. Ironclad electric switches.
15,006 KELVIN & JAMES WHITE (LTD.) EVANS & WILSON. Terminals for "shunts" and other electrical apparatus.
15,075 MACKENZIE. (Sundh Electric Co.) Electric circuit closing contacts.
15,115 REGNART. Electric reflector lamps.
15,151 LYNESS. Contact finger for electrical controllers and switches.
15,193 SOC. FRANCAISE D'INCANDESCENCE PAR LE GAZ (SYSTEME AUER). Preparation of filaments suitable for incandescent electric lamps. (Date applied for, 18/7/08.)
15,802 BROOKS & ALSTON. Electric ignition apparatus for internal-combustion engines.
15,881 JABURG. Arc lamps. (Date applied for, 1/7/08. Originally included in No. 7,471/09.)
16,292 MESSENIE & SLAUGHTER. Arc lamps.
16,331 MORRISON. Electric transmission for motor vehicles.

COMPANIES' MEETINGS AND REPORTS.

BARBADOS ELECTRIC SUPPLY CORPN. (LTD.)—At the statutory meeting on Wednesday Mr. L. W. Hawkins stated that the electric lighting order to acquire which the company was formed was sanctioned by both branches of the Barbados Legislature in May. The reports from the company's manager and the consulting engineer as to the demand for electrical energy were encouraging. The greater part of the plant and materials required for the equipment of the undertaking had been ordered. A site had been secured, and it was anticipated that construction would shortly commence.

BROWN, BOVERI & CO., (BADEN) A.G.—The net profit for the past year was 2,142,122 fr., against 2,752,809 fr. in the previous year, and a dividend of 8 per cent., against 11 per cent., was declared. The directors' report states that in spite of some revival in demand prices fell steadily throughout the year, and are still unsatisfactory. Every order is keenly fought for, and quotations are approaching levels which leave no margin of profit. The German market is particularly bad in this respect. The prices of steam turbines are poor, and the company have curtailed their output in the department. The French branch of the company has just received an order for six 20,000 H.P. turbines for the generating station in Paris. The company is engaged in working out simpler and cheaper models, which they think will prove satisfactory. Little or no progress is being made with the electrification of the Swiss railways, and but few generating stations are now being erected in Switzerland. The Prussian State Railways have ordered one of the company's electric locomotives and have shown great interest in their single-phase a.c. system, which is being largely adopted by mining companies.

CENTRAL LONDON RAILWAY CO—At the meeting last week the chairman (Sir Henry Oakley) said that during the past half-year their business had gone on steadily. They had earned £4,597 more and had saved in working £1,974. They had recommended 3 per cent. on ordinary stock and 4 per cent. on preferred ordinary stock, after providing for the interest on debenture stock, and they carried forward £40,000 for the dividend for the first half-year on the deferred stock. They were, therefore, for the time, in a happy and comfortable position. They were gaining slowly. They had carried an increased number of passengers (1,675,787) in the half-year, but as the fares were so small it took a great many millions of passengers to earn a substantial sum. The increase in the number of through-booked passengers to and from their line and other tubular lines was encouraging. They carried 420,000 more through-booked passengers in the last six months than in the corresponding period. The penny passengers had increased by 2,290,390. They charged 1d. for three stations, and the policy adopted had certainly developed a large local traffic. They had gained nearly 9 per cent. in passengers, but only 2 per cent. in money. Their capital expenditure was partly in replacing the original wooden platforms with stone and improving some of their machinery at Shepherd's Bush, so as to lessen, as far as possible, the cost of working and generating power.

ELECTRIC WELDING CO. (LTD.)—The accounts for the year ended Nov. 30 show a loss of £2,028 (including £1,176 for debenture interest), increasing the debit to balance of profit and loss account to £31,458.

GREAT CENTRAL RAILWAY CO.—At the meeting on Friday the chairman (Sir Alex. Henderson) said that there was a moderate increase in the number of passengers carried, though a larger increase had been anticipated in view of the improved business of the country. He had reason to believe that improved telephone service had affected railways, as journeys upon business by rail had become less necessary than formerly. There had been an increase in the number of season tickets issued, and a total increase under the head of passengers of £8,888. There were also increases in goods, parcels and minerals. In regard to the Altrincham line, which was a joint line belonging to the L. & N.W. and G.C. Cos., they had for some time past been considering with the L. & N.W. Co. whether it would be advisable to electrify the line. They had not yet quite decided what to do. The proprietors knew perhaps of the success which had attended the efforts of the Brighton line to get back traffic which had been taken by the tramway company, and it might be that other companies would follow suit.

HENDON ELECTRIC SUPPLY CO. (LTD.)—At the recent meeting it was reported that the result of the working for 1909 was a credit balance of £1,095. 1s. 7d., and after providing for interest and taking into account the debit balance from the previous year (£1,479. 9s. 3d.), the total debit was £1,970. 9s. 3d. On Dec. 31, 1909, 830 houses (with 23,055 33-watt lamps) were connected (against 343 houses and 12,058 33-watt lamps in 1908, and applications were in hand for 287 houses with 5,123 lamps.

HONG KONG & SINGAPORE TRAMWAYS.—At the recent meeting of the Yangtse Valley Co. (Ltd.) the chairman (Mr. Edmund Davies) said the company's principal interest remained in the Electric Traction Co. of Hong Kong, and, owing to the proposals passed by the shareholders in that company, the nominal value of the shares which the Hong Kong Company held would be reduced from £1 to 5s. each, and the debenture issue of the company would be increased from £195,000 to £205,000, as it was necessary to raise additional capital to provide further rolling stock and a site for the erection of car accommodation. The receipts show satisfactory increases, and from Jan. 1 to July 16 they were to $268,824, compared with $244,610 in the same period last year.

The receipts of the Singapore Electric Tramways from Jan. 1 to July 16 were $277,452, comparing with $269,470 for the corresponding period of last year.

LIVERPOOL OVERHEAD RAILWAY CO.—At the meeting on Tuesday Sir Wm. Forwood said the directors were gratified in being able to produce a slightly more favourable report for the past half year. The expenditure of the half year had been reduced by £524, and with an increased revenue of £824 there was an improvement of £1,348. The directors had been able to pay the 5 per cent. dividends on both classes of preference shares, leaving £5,916 to be carried forward. That was the first time since 1907 that they had been able to pay a dividend for that half-year on the second preference shares.

LONDON, TILBURY & SOUTHEND RAILWAY CO.—At the meeting last week the chairman (Mr. A. L. Stride) said that electric traction was very satisfactory, and 41,000 additional car-miles had been run. It was thought they had done well in 1909, when they ran a service at 2·77d. per car-mile; but for the half-year just ended the car-miles were run at 2·39d., or ⅞ths of a penny per mile less cost than last year.

METROPOLITAN DISTRICT RAILWAY CO.—At the meeting on Wednesday the chairman (Sir Geo. S. Gibb) said that they had carried 36,000,000 passengers during the past half-year, or an increase of 3,250,000; the passenger receipts were £280,000, an increase of £26,000 (about 10½ per cent.) The average receipt per passenger has been 1·86d. The season ticket revenue continued to show a good increase (£8,389, or 29½ per cent.), and the increase of traffic was again general throughout the system. They had had an increase at practically every station except a few of the stations on the east side of the City. The working expenses show a decrease of 3¼ per cent. Train working showed a decrease, mainly due to the very large saving in the cost of electric current. On the last occasion he mentioned that they were arranging an alteration of the supply agreement in regard to the depreciation fund. The power-house depreciation was originally arranged on the basis of 2½ per cent. on the total capital expended, including machinery, land and buildings. Now that the depreciation fund amounted to £148,000, it was plain that the figure set aside was substantially in excess of any reasonable calculation for depreciation. Therefore, they had arranged, with the sanction of the trustees for the power house debentures, that in future the amount to be set aside should be a fixed sum of £20,000 per annum instead of an average of about £35,000 per annum at present. The main factor in the saving was that they had got rid of the Westinghouse steam turbines that were originally installed at the power-house, and had installed in their places Parsons' steam turbines which were giving most excellent results. The cost of coal had not contributed to the saving, because in the half-year the average price of coal had been slightly higher than in the corresponding period of 1909. With regard to train working, the net result was a decrease of £1,500, and the total working expenses showed a net decrease of £4,765. After dealing with the various items in the accounts he gave a sketch of the steady progress made during the last 4½ years. Their capital account now showed a credit of £99,980, the renewal reserves amounted to £30,452, and there were unissued Prior Lien Debentures which could be issued for any necessary expenditure. Therefore, they might regard the financial position of the company with equanimity. In the last nine years the District Co. had been saved from wreck, and he could say with confidence that, except with regard to the rolling stock—which he did not like to permit himself to praise—the proprietors possessed one of the finest underground railways in the world.

MIDDLETON ELECTRIC TRACTION CO. (LTD.)—At the recent meeting it was reported that the revenue for 1909 was £17,273 and the expenses (including £2,000 for debenture interest and £1,000 for renewals) £15,680. The balance was £1,593, added to £1,507 brought forward.

PEARSON FIRE ALARM (LTD.)—The report for 1909 states that there was a profit on sales, rent of installations, &c., of £5,105, against £5,964 in 1908. After meeting expenses, paying debenture interest, &c., and allowing for depreciation, &c., there was a deficit of £2,677, against £39 in 1908.

TYNESIDE TRAMWAYS & TRAMROADS CO.—At the meeting on Tuesday the chairman (Dr. J. T. Merz) moved the adoption of the directors' report for the half year ended June 30, which stated that the profit was £3,656. 5s. 5d., which, with the balance forward (£521. 5s. 4d.) made £4,177. 10s. 9d. Deducting interest, &c. (£1,033. 2s. 11d.), the available balance was £3,144. 7s. 10d. After paying preference dividend the directors recommended a dividend on the ordinary shares at the rate of 1 per cent. per annum, and £643. 13s. 8d. is carried forward. The traffic receipts showed an increase for the half-year of £145. 9s. 11d.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES.

NEW COMPANIES.

C. H. HARE & SON (LTD.) (110,911.)—Reg. July 21, capital £12,000 in £1 shares, to carry on the business of mechanical, electrical, sanitary, lighting, heating, water-supply, civil and general engineers, &c., and to adopt an agreement with the Caribonum Co. (Ltd.), Sophia R. Hare and F. C. Hare. First directors, F. C. Hare, Sophia R. Hare and C. H. Mortimore, R. Clark and J. M. Evans.

JOHN RATTRAY & SON (LTD.) (7,609)—Reg. in Edinburgh, on July 12, capital £4,000 in £1 shares, to take over the business of gas-fitters and electrical engineers, &c., carried on by John Rattray & Son, Glasgow. Private company. First directors, G. McKinlay and H. R. Hayes.

M. & G. TRUCK & ENGINEERING CO. (LTD.) (111,131.)—Reg. Aug. 2, capital £5,500 in 5,000 preference shares of £1 each, and 10,000 ordinary shares of 1s. each, to carry on the business of electric and tramway, railway, constructional and general engineers as formerly carried on by Mountain & Gibson (Ltd.) at Elton Fold Works, Bury, and to adopt an agreement with Hobdell, Way & Co. Private company. First directors W. F. Hobdell (chairman) and I. E. Winslow (both permanent).

T. F. SYND. (LTD.) (111,205.)—Reg. Aug. 6, capital £2,000 in £1 shares, to carry on the business of manufacturers of and dealers in and agents for metal filaments for electric lamps, electricians, electric lamp and accessory manufacturers, suppliers of electricity, &c., and to adopt an agreement with the Deutsche Glühfahdenfabrik (Berlin), R. Kurtz and Dr. F. Eisner (the partners therein), and others. Private company. First directors, E. C. Churchword, Dr. F. Eisner, J. Wertheim and T. F. Wilson. Reg. office, 341-5, Birkbeck Bank Buildings, London, W.C.

TITAN ELECTRIC CO. (LTD.) (111,191.)—Reg. Aug. 5, capital £80,000 in 7,998 shares of £10 each, and 20 shares of £1 each, to carry on the business of engineers, &c., and to adopt an agreement with S. de Szepczynski for the acquisition of a business of manufacturers of electric batteries and accessories. Reg. Office, 792, Salisbury House, London Wall, E.C.

STATUTORY RETURNS.

CALLENDER'S CABLE & CONSTRUCTION CO. (LTD.)—In return to July 18 capital is £500,000 in 60,000 ordinary and 40,000 preference shares of £5 each. 35,000 ordinary and 40,000 preference shares taken up. £5 per share called up on 15,000 ordinary and 40,000 preference. £275,000 paid. £100,000 considered as paid on 20,000 ordinary. Mortgages and charges, £300,000.

EASTERN & SOUTH AFRICAN TELEGRAPH CO. (LTD.)—In return dated May 25 capital is £600,000 in £10 shares. All shares taken up. £600,000 paid. Mortgages and charges, £199,500.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.) By return, dated May 20, capital is stated at £3,000,000 in £10 shares. All shares taken up and paid for in full. Mortgages and charges, £752,400.

LEEDS ELECTRIC CO. (LTD.)—Return to May 20 gives captial £10,000 in £1 shares. 6,104 shares taken up. £2,800 paid and £3,304 considered as paid. Mortgages and charges, nil.

SOUTH LONDON ELECTRIC SUPPLY CORPN. (LTD.)—Return dated March 29 gives capital as £260,000 in 65,000 shares of £4 each. All shares taken up. £260,000 paid. Mortgages and charges, £100,000.

WEST COAST OF AMERICA TELEGRAPH CO. (LTD.)—Return to May 24 gives capital as £132,520 in 53,008 shares of £2. 10s. each. 45,008 shares taken up. £2. 10s. per share called up on eight. £20 paid. £112,500 considered as paid on 45,000. Mortgages and charges, £170,000.

WESTERN TELEGRAPH CO. (LTD.)—According to return dated May 25 capital is £2,500,000 in £10 shares. 207,930 shares taken up. £10 per share called up on 130,000. £1,300,000 paid. £779,300 considered as paid on 77,930. Mortgages and charges, £815,175.

MORTGAGES AND CHARGES.

G. W. CLARKE & CO. (LIVERPOOL) (LTD.)—Particulars of £1,000 debentures, created July 12, have been filed, the whole amount being now issued. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

I. T. C. (LTD.)—Particulars of £3,000 debentures, created April 23, have been filed, the whole amount being now issued. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

RAIL-LESS ELECTRIC TRACTION CO. (LTD.)—Issue on July 20 of £750 debentures, part of a series of which particulars have already been filed.

CITY NOTES.

MEMORANDA (Aug. 11).—Bank rate 3 per cent. (since June 9, 1910). Price of silver, 24⅞d. per oz. Consols 80⅞—81⅛ for money; 81—81⅛ for account. Consols Pay Day, Sept. 1; Stock and Shares Continuation Days, Aug. 29 and Sept. 13; Ticket Days, Aug. 30 and Sept. 14; Pay Days, Aug. 12 and 31; Mining Shares Carry Over Day, Aug. 26.

PRICES OF METALS (London).—*Copper*, cash, 55½; three months, 56⅛. *Lead*, English, 12⅞—13; foreign, 12⅝—12¾. *Spelter*, 22½. *Tin*, English, 150½—152½; foreign cash, 152½; three months, 152¾. *Iron*, Cleveland, cash, 49/11, three months, 50/8.

COMPANY REGISTRATIONS IN 1910.—The last issue of the "Investor's Guardian" contained a review of the company registrations of the first six months of 1910:—The number of companies registered (3,744) created a record, and, compared with the first six months of 1909, showed an increase of 31 per cent. The capital was £131,323,000, a sum more than double the average of the past five years. The capital of the rubber companies registered was £36,628,000 and of the oil companies £24,880,000. Mining registrations also show revival, the capital being the largest for five years. Engineering registrations have been steady, but electrical enterprises are still very depressed; motor and carriage registrations have also dropped to the lowest level.

METALITE (LTD.)—It is announced that the first batch of letters of allotment and regret for the recent issue of capital by this company has been posted.

WASTE HEAT & GAS ELECTRICAL GENERATING STATIONS (LTD.)—The directors have decided to pay an interim dividend at the rate of 5 per cent. (less tax) in respect of the half-year ending July 31.

NOTES.

International Electrotechnical Commission.

THAT the deliberations of the International Electrotechnical Commission have so far been productive of but small results, at any rate of a practical nature, is doubtless largely due to the comprehensive nature of the Commission, most of the important countries of the world being now represented at its Conferences. Progress, however, is nevertheless being made; and from our report of the proceedings at the unofficial Conference held at Brussels last week it will be seen that several decisions of considerable importance to electrical engineers are likely to be reached at the formal meeting of the Commission next year. In fact, the proceedings were so harmonious that the various proposals discussed will probably be adopted, without any serious alterations, by the various national Committees, and further matters will, doubtless, come up for consideration at the formal meeting next year after these proposals have been officially promulgated.

ONE of the most important subjects dealt with by the members last week was the question of symbols. The great disparity shown in those adopted by authors in different countries, and even in the same country, leads to much confusion, so that uniformity is much to be desired. In this connection it will be seen that, besides suggesting definite principles as to the use of capital, small and script letters, and in the use of the suffix "*m*," the Conference proposed the adoption of eight symbols, subject, of course, to the approval of the various Committees and of the official delegates next year. It may at first seem curious that μ is not included in the list of symbols, as it is practically universally used to denote permeability, but in view of the fact that its use in this connection will probably continue, and that it would form an exception to a principle likely to be introduced at a later date—viz., that Greek letters should be reserved for angles—it was considered desirable to omit μ from the list of symbols at present suggested. The proposed adoption of a standard direction of rotation for vectors is also worthy of note. We believe that opinion generally favours the anti-clockwise direction, which is in keeping with trigonometrical notation, although several writers have adopted the opposite method of representation.

ONE result of the unofficial Conference is that the full meeting of the Commission, which it had been arranged should be held at Berlin next year, will probably take place at Turin at the same time as the Electrical Congress which is to be held in connection with the Turin Exhibition. Members of the Commission will appreciate the courtesy of the German Committee in falling in with the proposed alteration in the place of meeting. An Electrical Congress is frequently associated with an international exhibition, but does not usually receive adequate official recognition; it is to be hoped, therefore, that co-operation will be possible between these two electrical bodies, to the advantage of both.

WE may also draw attention to the fact that a special invitation was issued to the secretary of the Engineering Standards Committee to be present at the meeting last week. In this connection, it will be remembered that Sir JOHN GAVEY and Dr. R. T. GLAZEBROOK were recently nominated to represent the Engineering Standards Committee upon the British Committee of the Electrotechnical Commission. This is extremely gratifying, for it evidences a desire on the part of the British Electrotechnical Committee to work in harmony with the Engineering Standards Committee. It may therefore be pre-

Digitized by Google

sumed that the excellent work already carried out by the Electrical Section of the latter body will be of great utility in forming the basis of the recommendations of the British section of the Commission when electrical machinery is under consideration. Moreover, it should further the recognition of the work of the Engineering Standards Committee.

The Association of Consulting Engineers.

THE chief bone of contention at the present moment in regard to the formation of the Association of Consulting Engineers is the question of qualification for membership. For the moment, membership is restricted to those who are corporate members of the Institution of Civil Engineers and also of the institution representing the particular branch of the profession in which they practice. In our correspondence columns this week Mr. H. LAWS WEBB questions the wisdom of such a rule, and this point has also been raised in other quarters. On a previous occasion we have expressed the view that any such rule would not be rigorously enforced, and we think it is only necessary for us to refer our readers to the official memorandum published last week, wherein it is stated that "*at present*" the membership is confined to those so qualified, for confirmation of our views. Mr. WEBB very rightly states that the man who has spent his life in some special line of work is better qualified than the average corporate member of the "Civils"; and we do not doubt that this point is in the minds of those most closely connected with the new Association. Obviously, the specialist should be welcomed by the Association; we would go further, and say that the specialist should give his whole-hearted support to the movement, for it is only by unanimous co-operation that the greatest benefit will result, and the profession of consulting engineering be given a proper status in this country.

IF only the critics of the rule in question will look at the matter broadly, we think they will find some wisdom in the course that has been followed. Reading between the lines of the official statements, it will be gathered that the required qualifications were so framed in the first instance as to make selection, or rejection as simple as possible. It may be contended that the experience and examination required by the "Civils" really count for very little in such a case. There may be some truth in this contention; but, in combination with other qualifications, they postulate a certain breadth of training, and the fact remains that most of the leading consultants *are* corporate members of the "Civils." It should be remembered that the formation of a society of this kind is not an easy matter, and that the elected committee have barely got to work. It would have been a fatal mistake to begin with a low standard, whereas to begin with a high standard (even if somewhat arbitrary), and then to adjust matters so that no injustice is done, is by far the safest course. For the success of the Association it is essential that the whole body of members should be satisfied that the members admitted are in every sense desirable; and, in working towards that ideal, we think the provisional committee were wise in adopting a rule which can, and must, be relaxed as soon as the Association gets into working order.

Brussels Exhibition Fire.

THE latest reports from Brussels as to the cause of the recent disastrous fire at the International Exhibition afford a complete refutation of the early report that the conflagration was of an electrical origin. The well-worn phrase, "the fusing of an electric wire," has been given very little prominence in the daily papers, and they must be complimented upon the exercise of a reserve which can only be characterised as remarkable, particularly in view of the magnitude of the electrical installation at the Brussels Exhibition, and the necessarily temporary nature of all the work. This reticence was, however, not imitated by our gas contemporaries, who, accepting a hurried and meagre report, announced to the skies the dangers of electric lighting. We deal with the details of the fire in another column, and it will be seen to reveal a sad, not to say criminal, lack of organisation in the Exhibition Fire Department, while they hint strongly at extreme laxity in the enforcement of the regulations regarding smoking in the buildings.

IT is unfortunate that such heavy loss has been inflicted on British exhibitors, especially as the majority of them had been persuaded to exhibit in the British section by the efforts of the Board of Trade Exhibition Department. The Commissioner-General, Mr. WINTOUR, and his assistants are to be commiserated on so untimely an end to their splendid efforts in making a thoroughly representative collection of British industrial and art exhibits. Still, the disaster has its lessons, dearly as they have been purchased. One of the most important of these, and one which strongly impresses itself upon us, is the folly—it can be given no other name—of massing the exhibits of a number of countries into what is virtually a single building. The Belgian, French, British and Italian exhibits were under cover of a contiguous series of buildings, and an outbreak of fire, unless promptly dealt with, would, as it has done, involve the entire series of structures. Absolute independence is the only safe plan upon which buildings should be laid down in exhibitions. The Germans adopted this method at Brussels, and their entire exhibit, self-contained and practically standing in its own grounds, remains to-day a striking monument either to their good luck or good judgment—more probably the latter. Had the British section been similarly dealt with there would be no national loss to mourn at this moment, and on parsimonious Government policy to deplore. However, no such calamity must overtake the British section at the Turin Exhibition to be held next year, and no doubt the Commissioner-General will see that there is no possibility of it.

Street Lighting in Westminster.

IT will be remembered that a month or two ago the Westminster City Council entered into fresh contracts with the Gas Light and Coke Company for the illumination of certain streets within the city area. Most of these streets are already lighted by gas, but one, Regent-street, has for some time been illuminated by a modern type of flame arc lamp. The electricity supply authorities were, it is true, also asked to tender for the lighting of the areas concerned, but the prices sent in by them were consider-

Digitized by Google

ably higher than those of the gas companies for an equal candle-power, and on these grounds, therefore, the tenders were not successful. At the time we went carefully into the question and formed the opinion that the prices quoted by the gas company not only left them no margin of profit but would involve them in a heavy loss—only 5½d. per 1,000 cubic feet being charged for gas, or about one-fifth of the *standard* price. It was evident, in fact, that they were determined to retain the street lighting at all costs, and to do this were willing to expend a large sum on what was really a form of advertising. These conclusions have turned out to be well founded, and during the last few days inspired paragraphs have been appearing in the daily papers stating that gas is to *supplant* electricity as a street illuminant in the business thoroughfares of the City of Westminster, except in the parish of St. George's, Hanover-square, and that this supersession is due to the fact that gas is from 30 to 50 per cent. cheaper than electricity. The insidiousness of these statements is evident; obviously it is not possible to supplant what was never there. In the whole area referred to something less than 100 arc lamps are to be removed in favour of gas, and, further, this form of lighting is only from 30 to 50 per cent. cheaper than electricity when the prices given in the Westminster tenders are taken as a basis of comparison.

A paragraph of the kind mentioned above, appearing in a widely read daily paper, is likely, and is probably intended by its inspirers, to cause a good deal of harm to the progress of electric lighting. It is, therefore, well that supply engineers and others who cater for public needs in the matter of electric light should be acquainted with the real nature of the campaign now being conducted by the gas interests, and should be prepared to controvert with figures such statements as those to which we have called attention. Our gas friends desire to have it both ways. They are willing, and are being allowed, to light Regent-street and Piccadilly with high-pressure gas at a wholly unremunerative price purely for the sake of advertisement. At the same time they wish it to be believed that they are doing this work at a profit, and are consumed with anxiety to persuade an unsuspecting public that some recent wonderful inventions in gas mantles have made this possible. But the "unsuspecting public" must be disillusioned. It is the duty of all who wish to further the cause of electricity supply to adopt for the nonce the rôle of the Ancient Mariner; and under those ghastly mantles which, unfortunately, we shall soon see in Regent-street, inform the world at large that this wonderful illuminant, of the supposed cheapness of which we hear so much, is only cheap when the customer is the street authority, and is both inefficient and expensive to the private individual.

Multiple Reflections of Short Electric Waves.—In a recent issue of the "Physical Review" Messrs. L. E. Woodman and H. W. Webb describe an investigation of the multiple reflections of short electric waves between two or more reflecting surfaces. The conclusions reached are summarised as follows:—(1) A Righi vibrator of small dimensions mounted with no oil holder surrounding the balls and with as little dielectric as possible in front of the aperture of the mirror and placed at the focus of a paraboloid of revolution acts very nearly like a point source and gives very nearly a parallel beam of energy. (2) The tuning curves as well as the wave-length curves show that the radiation from a Righi vibrator consists of a short spectrum of wave-lengths, and that the maximum on the tuning curves is governed within the limits of this spectrum by the peculiarities of the receiver. (3) The non-selective receiver is far superior for all work involving the determination of wave-lengths or the tuning of resonators pasted on screens and placed in the path of the incident energy. (4) The intensity of the transmitted and reflected energy passes through a series of maxima and minima as the distance between the reflecting surfaces is increased through a small number of wave-lengths (this agrees well with the theory as worked out for optics). (5) A screen of resonators acts like a selectively reflecting surface for waves very nearly in resonance with the resonators. This was tested by determining the wave-length of the transmitted beam as well as of the reflected beam. These were found to check at least qualitatively with what one would expect from a consideration of an assumed emission curve for the vibrator combined with an assumed transmission curve for the screen of resonators. (6) With a tuned receiver *extra-transmission* may be expected for plates of glass of the proper thickness and of the proper dielectric constant and for wave-lengths within proper limits. (7) The transmittivity of a glass plate of a given thickness and given dielectric constant depends upon the wave-length of the incident energy. (8) The change of phase due to reflection is not a constant, but varies with the length of the resonators pasted on the reflecting surface.

Electric Traction in Pittsburg.—Following on his report on this subject, a summary of which was published in our issue of August 5th, Mr. B. J. Arnold has now issued some further notes after a consideration of the various problems involved. The questions discussed are mostly to do with traffic, and include the author's view on how best the municipal authorities, the public and the tramway company can work together to obtain the most satisfactory service. His conclusions are: The public should learn to recognise that empty seats cost as much to operate as occupied seats, that a seat for every passenger during the rush hours must mean the curtailment of the service during the non-rush hours, and that new cars and new tracks cannot be furnished until the old rolling stock has been in service a reasonable length of time. The company should adopt the policy of trying continually to please the public, and should arrange their schedules and routes to accommodate the greatest number. If the best service can be rendered by establishing through routes and giving transfers, these methods should be adopted in an effort to increase gross earnings by making it easy to ride. The municipal authorities should co-operate with the company on street traffic regulation, widening the streets where necessary and issuing permits for extensions and new connections which are absolutely necessary for the best routing system. Unnecessary taxes and the burden of paving maintenance should be removed in the interest of allowing more money for better service. The property owner should recognise that the general prosperity of the entire district is not only vital to him but to others, and that routes and extensions cannot be controlled for his particular benefit. The financier must realise that the day for exploitation of established enterprises has passed, and that the fixed charges on such properties must be reduced to a fair return on the actual investment. New capital which is absolutely necessary for the continued life and usefulness of any public utility must be furnished, and this flow of new blood should be supplied in advance of actual needs, if it is to have a strengthening influence on the system. Economy and a continuation of an equitable balance dictates efficient management, and the setting aside out of earnings each year of a fund to provide for renewals. These conclusions are not unworthy of general attention in this country, where the tramway company is too often bled by the local authority, and the service conducted irrespective of the requirements of the public.

Constantinople.—The Chirket-i-Hairie Co., of Constantinople, have decided to rebuild and re-equip their shipbuilding yard and engineering works, to bring them up to date. The new buildings will cover an area of some 12,000 sq. yds. Two new slipways are to be erected in the yard, and new machine tools to be installed throughout, including two 20-ton overhead travellers and some 40 to 50 electric motors. The whole of the works will be electrically driven while the yard will be electrically illuminated. Gas engines and gas producer plant will be installed, and the whole of the equipment is to be ordered from England.

Accidents in Mines.—The annual report for the year 1909 of Mr. R. A. S. Redmayne, Chief Inspector of Mines, which was issued last week, shows that the total number of fatal accidents in the coal mines of the United Kingdom last year was 1,182, compared with 1,138 in the year 1908. These accidents involved the loss of 1,453 lives, as against 1,308 in the previous year. Only 11 of the accidents, involving the death of 13 persons, are attributed to electrical causes. Electrical accidents are accountable only for about 1 per cent. of the total number of fatalities, and in all cases they occurred underground. The number of deaths in 1908 due to electricity was 15, four of these being above ground. Last year's electrical fatalities therefore show a decrease of two compared with those of 1908. As regards non-fatal accidents, 153,306 persons were disabled for more than seven days, compared with 141,851 in the previous year. Of this large total, electrical causes account for 38 cases of injury to persons working underground, and in 18 cases to workmen above ground, the figures for last year being 22 and 12 respectively. The proportion of accidents attributable to electricity is therefore 0·4 per cent. In the case of metalliferous mines, no fatal accidents and one instance of injury are stated to be due to electricity, the total number of accidents in this class being 40 killed and 1,434 persons injured. The third heading under which accidents are classified is "In and about quarries"; 84 deaths and 4,856 cases of injury are recorded, electricity being in no instance responsible.

On the Decrease of Velocity of the β Particles on Passing through Matter.—Mr. W. Wilson recently discussed further details of this subject before the Royal Society, having in a previous Paper shown that the velocity of β-particles suffered an appreciable decrease on passing through matter. The present experiments were undertaken with a view of directly confirming this result. Homogeneous beams of rays were separated by means of a magnetic field from a heterogenous beam given out by the active deposit from radium. These homogeneous rays passed into another magnetic field, where their velocity was measured. Sheets of aluminium were then placed in the path of the rays between the two fields, and the velocity of the emergent rays was found to have decreased by an appreciable amount. From consideration of the law of absorption found to hold for homogeneous rays, the decrease of velocity of the rays as they passed through matter could be calculated, and was found to agree with the results obtained experimentally. The results obtained were in agreement with the equations $E = k(a-x)$ and $E^2 = k'(a'-x)$, where E was the energy of the rays, x the thickness of the matter traversed and k and a constants. The agreement was rather better in the former case than in the latter: but the range of velocities considered was not sufficient to differentiate sharply between them. Although the change in velocity observed was only from $2{\cdot}85 \times 10^{10}$ to $2{\cdot}25 \times 10^{10}$ cm. per second, yet the change of the properties of the rays with respect to absorption was very large, the absorption coefficient of the former being $4{\cdot}9^{-1}$ cm., while that of the latter was $35{\cdot}2^{-1}$ cm..

Cable Interruptions.	Date of Interruption.
Assab—Perim	July 8, 1909
Malta—Tripoli	April 20, 1910
Reunion—Mauritius	May 20, 1910
Latakia—Palura	May 26, 1910
Obock—Djibouti	June 24, 1910
Bonny—Duala	Aug. 3, 1910
Hong-Kong—Macao	Aug. 15, 1910

Electric Power on the Rand.—In a recent issue the "Transvaal Leader" gives some particulars of the power station being erected at the Rosherville Lake for the supply of electrical energy and compressed air to the mines of the Eckstein and Rand mines groups. It is stated that the station when completed will be the largest turbine installation in the world, its capacity being about 106,000 H.P. Considerable use is to be made of compressed air and huge pipe mains for the transmission of the air are being laid. Each of the four turbine-driven compressors will deliver about 600 cubic metres of air at a pressure of 140 lb. per square inch, whilst the five A.E.G. turbo-generators will each be of a capacity of 12,500 k.v.a. at 5,700 volts. Eight Babcock & Wilcox boilers are being installed in each of the three boiler houses, which are situated at right angles to the engine room, whilst eight 80 ft. chimney stacks have been erected. It is expected that a supply of electrical energy will be available by the end of the present year, and several of the mines will by that time be ready for electrical operation.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. C. M. Dowse contributes an article on "The Use of Thermo-junctions for High-frequency Current Measurements."

An unofficial conference of the International Electrotechnical Commission was held at Brussels last week. Several important proposals have been put forward for consideration by the various committees.

We give a description of the new Post Office Telephone Exchange at Glasgow, which was opened on Saturday last.

It is stated that the disastrous fire at the Brussels Exhibition was due either to the imprudence of a smoker or to malevolence. The suggestion that it was caused by an electrical short-circuit has been dismissed.

An interesting report on the Wigan tramway undertaking has been made by Mr. C. W. Mallins, general manager of the Liverpool Corporation tramways.

New Technical School Regulations have been issued by the Board of Education.

In a recent invitation for tenders for electric power plant at Maribyrnong (Victoria) it was a condition that the plant must be of Australian manufacture. The contract has been let at £7,459 to the lowest tenderer.

The results of through tramway working between the London County Council and Croydon Corporation tramways are shown in a set of interesting figures on another page.

Interesting statistics of the trade of the United Kingdom with the Argentine Republic are given.

The development of the telephone in Denmark in recent years has been so rapid as to put that country relatively in the front rank of telephone users.

Contracts have recently been let in New Zealand for the work of clearing the bush to enable an extensive hydro-electric enterprise to be carried out.

Legal.—An unusual claim under the Workmen's Compensation Act was part heard before Judge Scully at Hastings last week.

Companies' Meetings, &c.—At the meeting of the London Electric Railway Co. last week Sir Geo. Gibb gave particulars of the progress made by the three tube railways of the Company. Each of the railways showed an increase of traffic, while the expenses had decreased.

The directors' report of the Underground Railway Co. of London states that the result of the past year's working shows a substantial improvement.

The directors' report of the Mersey Railway Co. for the half-year ended June 30 states that further progress has been made, the receipts having increased while the expenses show a decrease.

The directors' report of the Compania Alemana de Electricidad gives particulars of the rapidly increasing demand for electricity in Buenos Aires.

INSTITUTIONS AND SOCIETIES.

UNION INTERNATIONALE DE TRAMWAYS ET DE CHEMINS DE FER D'INTERET LOCAL.—The congress of this Society will be held at Brussels during the week September 5th to 10th, when a number of interesting tramway Papers will be read.

INTERNATIONAL ELECTROTECHNICAL COMMISSION.

An unofficial Conference of this Commission was held at Brussels last week from August 8th to 13th, the gathering numbering about 50.

The Conference was opened by Col. R. E. Crompton, C.B., after which Prof. Eric Gerard, of the Institute Montefiore, Liège, gave an address of welcome to the delegates and representatives, and said the Commission was to be congratulated upon the success with which it was meeting in the various countries. He explained that the present conference was in no way official, but was intended as a preparation for the official meeting it was proposed to hold in Berlin next year. The Belgian committee, he said, offered a very hearty welcome to the representatives from the various countries, and trusted that the Conference would fulfil its object and enable the Commission to show practical proof of its utility. The Conference, being unofficial, no definite resolutions would be come to; on the other hand, he hoped most useful propositions would emanate from the Conference to be placed before the various electrotechnical committees.

The question of nomenclature was first considered. Dr. E. Budde, representing the German committee, put forward a list of about 80 terms. This aroused much discussion. It was fully recognised that the work already carried out by the British, French, Italian and other committees who had for the past year or two studied the question of an electrotechnical vocabulary, was of great value, and that the question of the vocabulary was one which was and would always form part of the work of the Commission. At the same time, in order to facilitate progress, the Conference decided to recommend to the various committees the idea underlying the proposal of the German committee, viz., to take a certain leading idea, for instance, an electric generator, and to describe its various parts, each committee being subsequently asked to give the term in French and English and in their own language for each particular part described. Each committee are to send their replies to the central office before March 1, 1911, and delegates from the British, French and German committees will meet before the following September in order to prepare a list of agreed definitions to be put before the Commission at its next meeting.

The conference also suggested that the French and Belgian committees working together should be requested to undertake the preparation of the logical list of fundamental ideas in such a manner that one definition leads naturally to the next. These definitions will be gathered into groups, certain leading ideas being taken as the starting point for each group.

The French representatives next put forward certain principles in regard to the question of symbols. These proposals, which are of great importance, came in for much discussion, but finally it was agreed that the following five principles should be submitted for the consideration of the various electrotechnical committees: (1) That small letters be reserved for instantaneous values of electrical quantities varying with the time; (2) that capital letters be reserved for effective or constant values of electrical quantities; (3) that capital letters followed by the suffix "m" be reserved for the maximum values of periodical electrical quantities; (4) that capital script letters be reserved for magnetic quantities, constant or variable; (5) that capital script letters accompanied by the suffix "m" be reserved for the maximum values of magnetic quantities.

The conference also agreed to suggest the following eight symbols:—

Electromotive force	E, e
Electrical quantity	Q, q
Inductance	$\mathcal{L}$
Magnetic force	$\mathcal{H}$
Magnetic flux density	$\mathcal{B}$
Length	L, l
Mass	M, m
Time	T, t

The omission of μ for permeability is noticeable. In view of proposals likely to be introduced at a later date, however, it was decided not to include permeability at the present stage especially as the use of μ for permeability is practically universal.

The question of the direction of rotation in the case of vectors was brought to the notice of the Conference by the American representatives. Dr. Kennelly read at the recent convention of the American Institute of Electrical Engineers a Paper dealing with this subject, and the convention have requested the Electrotechnical Commission to consider this with a view to giving an early decision on the matter. At the present unofficial meeting no recommendation was made to the electrotechnical committees on account of the many authorities who ought to be consulted in the various countries. The Conference, however, thought it was desirable that each committee should send to the central office a short report on the subject after consultation with those interested in the question.

A preliminary suggestion as to the rating of electrical machinery was finally put forward by the American representatives, but the Conference felt that they could not adopt the proposal as it stood. Feeling, however, the necessity of taking some step in this direction they suggested for the consideration of the various committees that the output of an electrical generator should be defined as the power available at the terminals, and that of a motor as the power available at the shaft; and, further, that electrical and mechanical power be expressed in international watts.

It may be remarked that in making the above expressions of opinion the Conference was unanimous.

The question of electrical congresses was also discussed. The Italian representative, Mr. Guido Semenza, drew attention to the international exhibition to be held at Turin next year, and to the fact that he had received a communication in regard to holding an electrical congress there. He said he was sorry the Commission was going to meet at Berlin and that there should be an electrical congress at Turin at the same time, for the Commission and the congress were doing much the same thing—working for the good of the electrical industry.

Dr. Budde, the German delegate, with the courtesy which has always distinguished his attitude at the meetings of the Commission, stated that although the German committee would certainly be extremely sorry if the Commission did not go to Berlin, it was certainly inopportune to hold a congress in Turin and for the Commission to meet in Berlin. If, therefore, it should be decided to hold an electrical congress at Turin, the German committee would be quite willing to waive their claim and to agree to the Commission holding its meeting at Turin.

The Belgian committee had made extensive preparations for the entertainment of the members of the Commission who attended the Conference, and their kindness was much appreciated. The programme included a lunch at the Exhibition, excursions to Liége and from there by boat to Cockerill's works, an excursion to the Société Electrique Charleroi and to two coal mines where an interesting electrical haulage on the Ward-Leonard system was inspected, a 30-ton flywheel equaliser being installed.

On the last day of the conference the members were most cordially received by the Burgomaster at the Town Hall of Antwerp. The proceedings concluded with a lunch, at which a very cordial telegram was received from the King of Belgium, who it is well known has strong leanings towards science of all kinds.

THE MOORE LIGHT.*

BY W. WEDDING.

The German Moore Light Co. asked the author to report on the installation they have erected in one of the public halls in Berlin. But as this was not very convenient in view of the many instruments and the large amount of apparatus that would be necessary, they installed the light in one of the large workrooms in the Charlottenburg Polytechnic, and the present report is based on the results so obtained.

D. McFarlan Moore first described his methods to the American Institute of Electrical Engineers on April 24, 1896,

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

and lighted the lecture room with 27 Geissler tubes, made in accordance with his methods. On this occasion he used tubes 2 metres long and 5 cm. in diameter. In 1903, using tubes 4·5 cm. in diameter, and 17·5 metres long, he carried out the lighting of some business premises in New York. He used a special type of alternate-current machine for producing a sudden change in the voltage: this is described in his German patent, No. 130,123 of January 21, 1900. At the present moment in America there are tubes 66 metres long. He now uses ordinary alternate current of a frequency between 40 and 60, relying chiefly on the German patents No. 150,095 of June 5, 1902, and No. 187,649 of May 3, 1906. The latter patent, which is the more important of the two, describes a method of preventing a variation of the vacuum in the tube. It is well known that this variation ordinarily takes place, unless means are taken to prevent it, and this constitutes the so-called "hardening" of the tube. Unless the vacuum is maintained at a steady value, the conductivity of the tube varies, and with it, of course, the light emitted. The device consists of a method by which a decrease of vacuum in the tube increases the conductivity; this causes an increase of current to react on the primary circuit, producing a similar increase there, with the result that a mercury-sealed valve is momentarily opened, allowing gas to pass into the tube, till equilibrium is restored.

Ordinarily the installation is built up out of 2-metre lengths of glass tubing, which are fused together *in situ*, the whole being suspended from the ceiling by insulated supports. Moore gives a good deal of detailed information in his last-mentioned patent, and there is much to be learnt from his lecture before the American Institute of Electrical Engineers on April 26, 1907, where he speaks of tubes up to a length of 70 metres. In the present case now under examination, the length of the tube was, in all, 37·5 metres. The walls of the tubing are 2 mm. thick, and its external diameter 44 mm. The

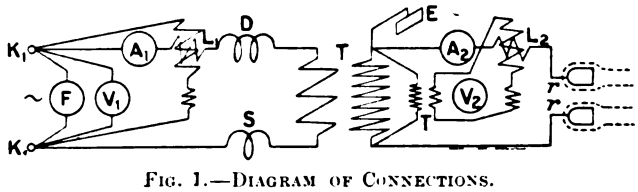

Fig. 1.—Diagram of Connections.

tube was suspended at a distance of 1 metre from the ceiling, and a Weber photometer was installed at this height for purposes of observation. In the first instance, central strips of the tube, 1 cm. broad, and of varying lengths, were examined, and it was found that, to all intents and purposes, the lengths of the exposed portion of the tube varied as the light emitted. The primary pressure was 220·6 volts, and that of the secondary 12,926 volts; with a frequency of 50, the light emitted per square centimetre was 0·21 hefner c.p. Similarly the light emitted through a circular aperture in a direction perpendicular to the length of the tube was roughly proportional to the radius of the aperture, the maximum value of which was about the same as the width of the tube. This leads to the question as to the extent to which the light is absorbed in its passage through the gas. This was determined by placing two arms of the tube immediately one behind the other, and finding the candle-power given out by the one alone, and then by the two together. In this way it was found that no light was absorbed by the column of the gas, which is therefore completely transparent, this being precisely the opposite effect to that produced by the ordinary bat's-wing gas burner. This effect can be observed by looking down the tube from one end, when the light seems almost as bright as that of a small arc lamp, whereas looked at from the side in the usual way it appears quite dull.

The question of the efficiency was examined with the connections as shown in Fig. 1. At the terminals K alternate current is taken from the mains, the tube being shown on the secondary side at *r*. L_1 and L_2 are wattmeters, E is an earth connection, D is a choking coil and S the solenoid working the automatic valve, which is placed in the primary circuit for greater safety in working.

The candle-power emitted through a circular aperture with a diameter of 1 cm. was found to be 0·571 hefner c.p., which gives a candle-power of 57·1 for the length of a metre. The total length of the tube was 37·5 metres, and the total power absorbed was 3,286 watts. Therefore, 87·6 watts correspond to 57·1 hefner c.p., or 1·53 watts per hefner candle-power. The overall efficiency between the primary and secondary terminals was 0·877, the frequency 50, the primary and secondary voltages 220 and 12,790 respectively, and the primary current 23 amperes, with a power factor of 0·647. If the losses which take place in transformer, choking coil, copper and iron are neglected, as having no real connection with the efficiency of the light, we find that 1 hefner c.p. is produced by 1·34 watts. This is very similar to the result produced by the metal lamps, and is still far from the ideal heatless light. The tube feels only slightly warm to the touch, but the radiation is, of course, spread over an immense surface, amounting in all in this case to 5·18 sq. metres. The effect of change of frequency in the given lamp was very marked. The primary voltage, which had to be kept constant, was therefore very low. The valve keeps the primary current constant, and the secondary voltage falls as the frequency rises. The watts absorbed by the secondary also sink, and with this is bound up the corresponding fall in the candle-power. Thus, with a constant primary voltage of 153 or thereabouts, and with a rise in the frequency from 36 to 60, there was a fall in the candle-power per metre length of 24·3 to 5·2. Owing to the insufficiency of the secondary voltage, the light flickered somewhat at the higher frequencies, and under these circumstances the higher frequencies require higher voltages. It must be said that the light shows a certain sluggishness in adapting itself to any change. When switched on it lights up at once, but after that any change in the conditions only makes itself felt slowly.

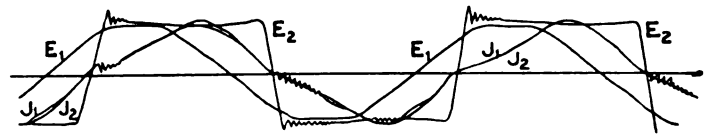

Fig. 2.—Oscillograms showing Primary and Secondary Voltages and Currents, the Secondary Waves being shown displaced through 180°.

Thus, a series of observations carried out at a given voltage does not always necessarily give the same mean result, as was found experimentally. This can probably be traced to the effect of changes slowly taking place in the conditions, but this sluggishness has its advantages in the fact that such changes as take place are quite unnoticed by the ordinary observer.

A series resistance has to be used with the Moore light just as with an arc lamp, and for this purpose a choking coil is used, which is provided with five terminals to meet the various cases that may arise. If the number of turns on the choking coil is increased the secondary voltage falls, and with it also the candle-power. On the other hand, if the choking coil is completely cut-out the flickering is such that it is impossible to use the photometer. Normally, the choking coil was found to take 140 watts, which is 4 per cent. of the total taken by the primary.

A series of oscillographic records is given, showing that the primary and the secondary currents are of almost exactly the same wave-shape, if differences of amplitude are neglected. There is no phase-displacement whatever between the waves of secondary voltage and current, thus showing that the gas column is free from anything of the nature of capacity or self-induction. There is no trace of any back E.M.F., and the tube may be said to constitute a simple inductionless resistance. The shapes of the curves are shown in Fig. 2, but the secondary waves have here been shifted back through 180 deg. in order to compare their shapes with those in the primary. The curves show that the gas column itself produces the sudden change in the secondary voltage which Moore supposed originally would require a special machine for the production of the primary wave. The shapes of the secondary

Digitized by Google

waves are shown very clearly in Fig. 3, and they are seen to be very similar to those obtained in the ordinary alternate-current arc lamp. The Moore arc lamp may therefore be considered as a type of the simple arc lamp, 37·5 metres long. Some further oscillographic records show the effect produced by a variation of the amount of self-induction in the primary. The most noticeable result is the effect produced upon the time taken by the secondary current to pass through its zero value, which is so prolonged in the case where the choking coil is almost cut out that photometric readings become impossible owing to the flickering. The valve also works n this case very unsteadily. In one instance the light broke down altogether, and this was probably due to the too rapid admission of air through the valve, with the result that it was not entirely freed from oxygen by its passage over the phosphorus.

A further experiment was made by lighting the same room with an installation of tantalum lamps, which were carefully adjusted to take the same amount of energy as the Moore tube. The room was 4·75 metres high, 17·4 metres long, and 8·6 metres broad; 41 tantalum lamps were required, each of 50 c.p., and one of 25 c.p. When the tantalum lamps were alight, the illumination was carefully mapped out over a number of points at a height of 96 cm. from the ground, a magnesia plate being used as the reflecting surface. The same was also done for the Moore tube at 26 points in the room, about six or eight readings being made at each point. The readings varied from 29·4 hefner c.p. to 48 hefner c.p., the mean value being 37·3, for the tantalum lamps; while for the Moore tube, the readings varied from 32·4 to 46 hefner c.p., with a mean value of 39·4. The uniformity of the distribution

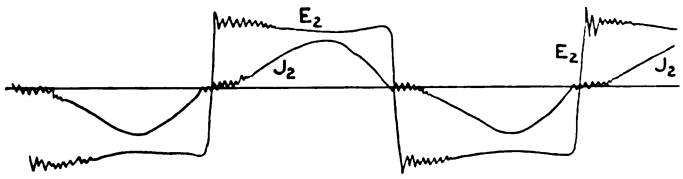

Fig. 3.—Oscillograms showing Secondary Voltage and Current, there being no difference of phase between the two.

was therefore slightly greater in the latter case, owing doubtless to the fact that the light-emitting surface is much more extended, whereas the tantalum lamps are, as it were, so many bright specks. This is one of the great advantages of the newer form of light, in that it tends to produce a well-diffused illumination, this object being to some extent attained in incandescent and arc lamps by the use of frosted bulbs and globes, which, however, shut off at least 10 per cent. of the light.

Further, the Moore tube gives a warm rosy light, which is very agreeable in a room. It must remain a matter for experiment as to whether nitrogen can be more profitably replaced by another gas. The cost of an installation must be compared with those using the ordinary method, and no doubt there is likely at first to be some difficulty in getting a sufficient number of experienced workmen, just as in the case of any other novelty of a similar kind. The high voltage ought not to be in itself a source of danger, seeing that the tube itself can be handled without any risk. Repairs are another matter. In case of breakage, a piece of tube would have to be cut out; but the Americans have to some extent foreseen these points, and arranged suitable apparatus for the purpose. Whether the supply companies will approve of the lag in the primary cannot be foretold; at present, a power factor of 0·6 is not unknown in the case of some power users. Its first application is likely to be found in lighting some of the larger buildings, but even so, some sort of stand-by would seem to be necessary. There are doubtless other points requiring further consideration, but the lamp may be taken as an interesting example of the attempt to convert energy into light without the manifestation of heat.

ON THE USE OF THERMO-JUNCTIONS FOR HIGH-FREQUENCY CURRENT MEASUREMENTS.

BY C. M. DOWSE.

Summary.—The author describes a form of thermo-junction suitable for radio-telegraphic measurements in technical colleges. "Eureka"-copper junctions have been found very suitable for the purpose. The particular construction adopted is described and tests are given showing that such junctions are reproducible and are reasonably permanent.

One of the most sensitive methods of measuring small alternating currents of high frequency is that in which the heat developed in a short, fine wire raises the temperature of a thermo-junction soldered to it, and the resulting thermo-E.M.F. is detected by a galvanometer of suitable resistance connected to the junction. If the diameter and length of the wire are kept small, variations in the effective resistance with frequency will be negligible.

Prof. Fleming and others have used and developed apparatus based upon this principle, and it is also embodied in the highly sensitive thermo-galvanometer of Mr. Duddell, where, however, the heating wire is not in contact with the junction. For use in the practical classes in radio-telegraphy at the Northampton Polytechnic Institute, it was found desirable to have some inexpensive, portable instrument for high frequency current measurements, having as long a range as possible, so that, if necessary, the same apparatus would serve for the determination of resonance and damping as well as currents up to 1 or 2 amperes. A suitable series of thermo-junctions in conjunction with a Paul unipivot galvanometer has been found to meet all requirements, and experiments will be described which indicate the possibility of standardising these junctions for general laboratory use.

Materials.—The table below gives some of the most suitable combinations, with the approximate thermo-forces. The differences between the values given by different observers for various samples of wires are so large that it is useless to give more exact results. In most cases, also, they refer to mean temperatures considerably lower than that employed in the case under consideration, and the thermo-forces will accordingly be different at the higher temperatures of the heating wire, except in the case of those materials for which the lines on the thermo-electric diagram are nearly parallel.

Materials.	Mean thermo-E.M.F. Micro-volts per deg. C. 0—150°C.
Antimony-bismuth	104
Copper-constantan	40
Constantan-iron	51
Nickel-iron	31
Copper-Eureka	41

The antimony-bismuth junction is very sensitive, but the mass of metal, and therefore the heat capacity, of the junction is fairly large, the high resistance of bismuth seriously reduces the galvanometer current, and the soldering is difficult and so unsatisfactory that the joint is liable to fracture by even a slight jar, and it is therefore better to use a more robust but less sensitive combination, and raise it to a higher temperature. Copper is a good material in conjunction with constantan or Eureka, as its resistance is low, and W. P. White * has shown that its thermo-electric properties are constant. The well-known alloy constantan has been largely used on account of the high thermo-E.M.F. against iron, but the properties of this substance are liable to serious variations in different samples, although there is no evidence of important secular changes in a junction containing it. A striking example of the variations referred to was met with when an attempt was made to obtain a second sample of a constantan wire having a remarkably low temperature coefficient, and a thermo-force against copper which was 35 per cent. higher than that usually obtained. This material is No. 9 in the list of properties of

* "Phys. Rev.," Vol. XXIII.

Digitized by Google

resistance alloys observed by Mr. Jolley and published * in a Paper by Dr. Drysdale. On testing the wire supplied by the manufacturers as the same material, the thermo-force against copper was found to be only 42 micro-volts per degree C. and not 57 micro-volts. A more serious difference is shown by the figures for this thermo-force given in a Paper by Mr. R. D. Gifford, M.Sc.,† where the remarkably low value of 17·7 micro-volts is recorded.

The iron-constantan couple is more difficult to solder effectively, but it has a much greater sensitiveness than a similar copper-constantan junction. This is clearly shown by the curves in Fig. 1, which were obtained by calibration, with a continuous current, of two similar junctions of copper (diameter 0·02 mm.) and iron (diameter 0·02 mm.) with constantan (diameter 0·016 mm.). The last-mentioned wire was used in the heating circuit, and the resistances of this and the junction circuits were adjusted to equality. The greater sensitiveness of the junction with iron is partly due to the low thermal conductivity of this material as compared with copper.

Nickel and iron junctions are not very sensitive and are troublesome to solder, but these materials have no neutral point above 0°C., and the lines on the thermo-electric diagram

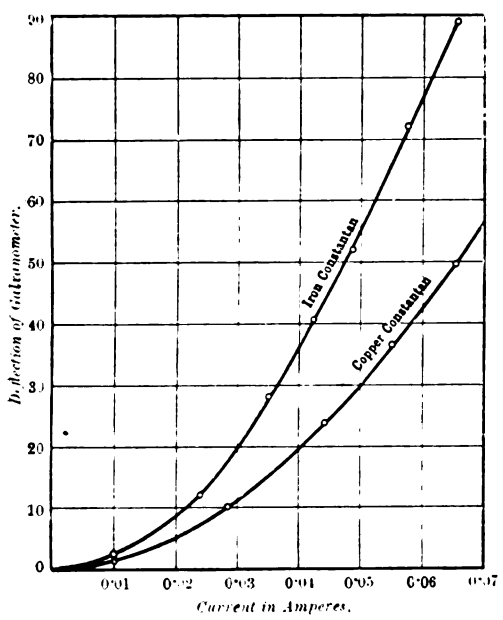

Fig. 1.

are almost parallel, so that the E.M.F. developed is fairly proportional to the difference of temperature. This is also the case with iron and german silver, and copper and constantan or Eureka. Eureka wire has been found from experience a very satisfactory material for this work. The thermo-force against copper is high, and has been found to vary but little in different samples.

The following experiments were performed in order to test this point. Three samples of Eureka wire with diameters of 0·13 mm., 0·33 mm., and 0·71 mm respectively, were each soldered to lengths of copper wire (diameter 0·27 mm.), and two of these junctions were immersed in an oil bath, the copper wires connected to a reflecting galvanometer, and the remaining ends of the two Eureka wires were soldered together and placed in another oil bath which was kept at a constant temperature. On raising the temperature of the oil surrounding the copper-Eureka junctions, any observed deflection would be due to a difference in the thermo E.M.F.s developed. Errors due to stratification were avoided by stirring constantly. In order to ascertain the sensitiveness of the arrangement, one copper-Eureka junction was transferred to the cold bath, and the deflection noted for a small known difference of temperature. From this, by assuming strict proportionality between E.M.F. and difference of temperature, the deflection for the highest difference of temperature can be obtained.

* The Electrician, October, 1907.
† "Electrical Engineer," Vol. XLV., p. 3.

The results are given in the accompanying table, and it will be seen that the differences are very small. One experiment was made with two junctions of the *same* wire with copper, and in this case the difference is even smaller.

Junctions in hot bath.	Difference of temp.	Deflection.	Calculated deflection for given difference.	Variation. %
Copper – Eureka ..... (d. = 0·27mm.) (d. = 0·33mm.) Copper – Eureka ..... (d. = 0·71mm.)	151°C.	10·0 divs.	1,033	1·0
Copper – Eureka ..... (d. = 0·71 mm.) Copper – Eureka ..... (d. = 0·13 mm.)	144·5°C.	9·5 divs.	1,034	0·9
Copper – Eureka ..... (d. = 0·71 mm.) Copper – Eureka ..... (d. = 0·71 mm.)	136·0°C.	1·5 divs.	3,040	0·05

Construction.—Although it is well known that the sensitiveness of a thermo-electric junction is considerably improved by placing it in an exhausted vessel, this refinement is not advisable in an instrument for general testing purposes, as repair is difficult and the resistance and decrement are necessarily high. The most convenient arrangement has been found to comprise two junctions mounted close together on a wooden or ebonite base.

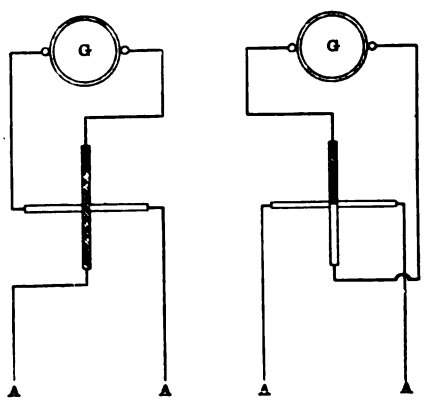

Fig. 2A. Fig. 2B.

The junctions may be adjusted to equal sensitiveness, when they may be used for differential tests, or they may have different ranges of sensitiveness to suit the conditions of the circuit.

The ends of the heating and junction wires are soldered to small copper wires which can be clamped in position, and a wooden cover with a glass lid prevents disturbance by air currents.

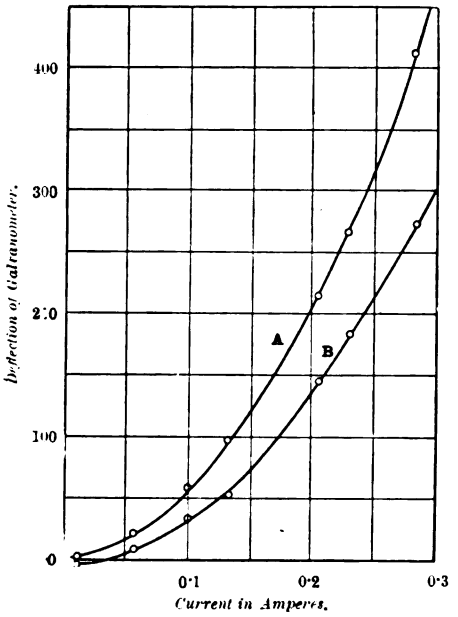
There are two ways in which these junctions can be made, which are indicated in Fig. 2, A and B. The first method has been used largely on the Continent and is the only type mentioned in Zenneck's well-known treatise.* Wires of two different materials are stretched between opposite terminals and soldered at the centre. The circuit in which the current is to be measured is joined to AA, and a galvanometer is connected to the remaining terminals, both circuits being composite. There are two disadvantages in this method of construction. In the first place, the hottest part of the high-resistance wire is not at the junction, and, secondly, it is necessary to take readings with reversed currents when calibrating, because of the Peltier effect. The magnitude of the difference in the resulting E.M.F. with the current in different directions in the case of a "crossed" junction of copper (diameter 0·07 mm.) and Eureka (diameter 0·05 mm.) is evident from Fig. 3. It will be seen that the cooling effect actually over-balances the ohmic heating for low currents. In the

* "Elektrische Schwingung und Drahtlose Teleg.," p. 777.

Digitized by Google

case of copper and Eureka, a crossed junction is not more than two-thirds as sensitive as one constructed in the second manner. In this case, a heating wire carrying the current to be measured is stretched between opposite terminals, but the junction wires are in a separate circuit and the two ends are soldered to the centre of the heating wire, as shown in Fig. 2 B. No part of the heating current now passes through the junction, but there is a possibility of an error in calibrating if the junction wires are not at the same point on the heating wire. This type is more difficult to construct than the crossed type, but it is much more satisfactory from every other point of view.

The chief trouble is in effectually soldering the three wires, as this cannot be satisfactorily done with an ordinary soldering iron when fine wires are used. After some unsuccessful attempts to effect the joint by passing a current through the heating wire, it was found that uniformly successful results could be obtained by the use of a small platinum heater shown in Fig. 4. Two stout copper rods, A, A, are fixed in grooves in a rectangular piece of ebonite, and the ends are bridged by a strip of platinum foil, B, bent into an arch. A current of



Curve A, Peltier effect assisting ohmic heating.
Curve B, Current reversed. Peltier effect opposing ohmic heating.

FIG. 3.

about 10 amperes from a few secondary cells is sufficient to raise the foil to a red heat, and the joint can be made without touching the wires.

The usual method of procedure is as follows: The wires to carry the tested current are soldered to two opposite lugs, and any slackness made up by sliding the lug through the terminal. The junction wires are also fixed to the remaining pair of copper lugs, and cut off to the required length. This should allow a little arch to be made in each, so that there is no strain on the joint owing to the expansion of the hot wire. The position of the ends of the wires is adjusted by moving the rods through the terminals, and they should be finally clamped so that the wires meet on the heating wire at the same point, with a slight downward pressure. The joint is now treated with a few drops of a solution of resin in pure alcohol, and a tiny fragment of solder placed on the point of contact. The red hot platinum foil is then placed under the junction and the solder will melt to form a sound joint. The process can be watched by means of a lens, and no difficulty has been found in carefully adjusting the positions of the junction wires while the solder is plastic. If properly done, no difference in deflection will be obtained on passing a current in different directions through the heating wire. Much depends on absolute cleanliness of the materials, but with care, wires of copper, Eureka and constantan, with diameters as small as 0·016 mm., can be soldered in this way, and of the 50 or more junctions which have been made—in some cases by students—not one has broken at the joint on account of mechanical injury.

Iron cannot be satisfactorily soldered with resin, and it has been found necessary to use a solution of zinc chloride as a flux. In this case, the junction is washed with sodium carbonate after soldering, and finally with distilled water. It is, however, very probable that the zinc chloride would lodge in microscopic pockets inside the joint and eventually cause corrosion of the material.

Messrs. Hartmann & Braun supply very fine wires of constantan, iron and other metals, but they are difficult to handle, because of a tendency to curl. This can be prevented by holding a piece of the wire above a small bunsen flame until it is raised to a red heat, after which it can be pulled straight with ease. The film of oxide can be removed by immersion in dilute nitric acid and washing.

Standardisation.—Since momentary rushes of current are liable to occur in adjustable resonating circuits, and it is practically impossible to protect these fine wires by fuses, it seemed advisable to determine how far it was possible to accurately reproduce junctions having approximately similar calibration curves, and which could be relied upon for permanence under normal and overload conditions for a reasonable time.

In this connection three questions must be considered:—

1. The similarity in properties of various specimens of the same material.

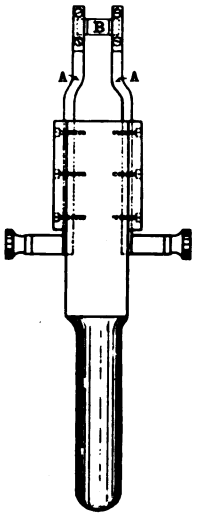


FIG. 4.

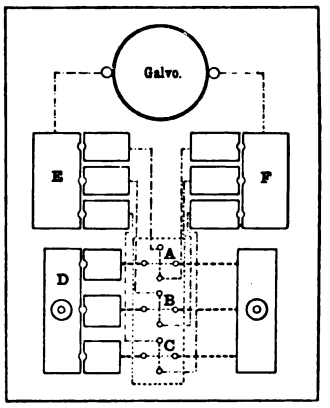

FIG. 5.

2. The most satisfactory size and form in order to secure accurate reproduction.

3. The constancy of the calibration under varying conditions of use.

Experiments have already been described which show the properties of Eureka wire to be fairly constant, and the writer would therefore recommend the use of that material in preference to constantan. For this special purpose, sensitiveness must be sacrificed for constancy and reliability, and iron and constantan are therefore not admissible.

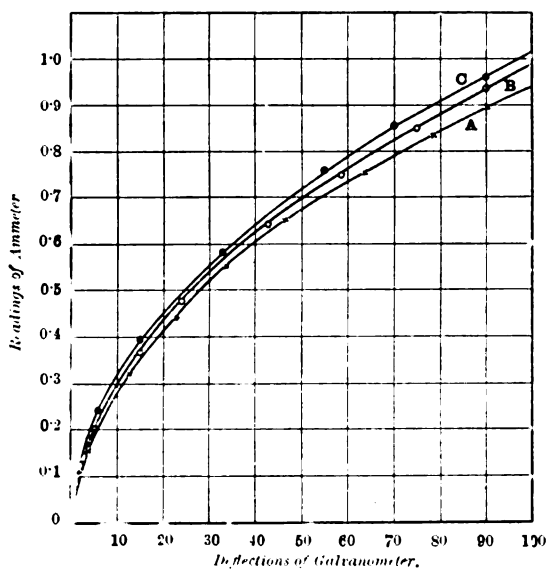
The size of the heating wire must depend upon the maximum current it will carry, but as the properties of Eureka, and indeed of most alloys, are changed when they are submitted to temperatures above 500°C.—600°C. for any considerable time, the maximum temperature must be kept low. For standardised junctions the joint should be hard soldered, if possible, as there is less danger of melting the solder or of changes in the thermo-force. The length of the wire must be kept as small as possible to reduce the inductance, but conduction to the terminals will reduce the sensitiveness, and the best length for the heating and junction wires can be found by trial. After a little practice, it was found quite easy to reproduce a number of junctions having calibration curves which differed by not more than 1 per cent. at any part of the scale. The heating wires were adjusted to the same resistance, and the lengths of the junction wires made equal. On solder-

Digitized by Google

ing and testing, any differences due to varying mass of solder at the junction were compensated by varying the length of the Eureka junction wire, and this has been successfully done with wires of 0·016 mm. diameter where the mass variation is very important.

Since it is undoubtedly possible to reproduce standard junctions, the only remaining question is that of permanence. It is true that continued heating at excessive temperatures renders most materials brittle, and changes would certainly occur in the thermo-E.M.F., but the writer is of the opinion that the unreliability of junctions of suitable materials has been exaggerated, and experiments have shown that with proper precautions serious variations can be avoided.

Two similar combinations of copper (diameter 0·035 mm.) and Eureka (diameter 0·05 mm.) were made up and a continuous current of 0·7 ampere was passed across the heating wire of one, while the deflection of a galvanometer attached to the junction was compared at intervals with that obtained from the second junction which was not continuously in circuit. The heating wire was of Eureka (diameter 0·1 mm.) and the current passed was 75 per cent. of that required to cause a dull red glow, but no change in deflection could be detected after the current had been flowing for three weeks. The current was then increased until the segments of the heating wires between the junction and the terminals showed a dull red glow at the centre, and this temperature was maintained for half an hour.



A, Continuous current. B, $n = 2{\cdot}3 \times 10^6$. C, $n = 3{\cdot}1 \times 10^6$.

FIG. 6.

The deflection at the end of this time was 2·8 per cent. lower than before for the former current, and this is very satisfactory considering the severity of the overload.

Junctions have been used on high-frequency circuits for long periods, and no serious changes in their calibration have been observed, provided that the wire was not overheated. We may therefore conclude that copper-Eureka junctions are reliable, reproducible and fairly permanent, and are very suitable for high frequency measurements. As a result of these experiments it is evident that an accurate instrument of considerable range and flexibility can be constructed by combining a series of standardised junctions with the necessary plug switches and a suitable galvanometer. The arrangement is seen in Fig. 5, where A, B and C represent three junctions which can be placed separately in circuit by the plug switch D. The junction wires are joined to the galvanometer by the plug switches E and F.

The circuit including the heating wire is as straight and short as possible, and the connections should be made with stranded wire. The whole junction circuit may be examined by means of a sliding base, and in the event of a junction being burnt out it can be quickly replaced by another having the same calibration. The galvanometer might have three scales, or the calibration curves could be placed inside the lid.

Such an instrument has several advantages over the ordinary hot wire instrument.

1. The range is easily varied.
2. The energy consumption is smaller.
3. Action is less sluggish.
4. The readings are independent of frequency.

It is difficult to determine theoretically the variation in resistance of a small wire, because the value of $\sqrt{h}$ in the formula given by Prof. Fleming,* $\frac{R'}{R} = \frac{1}{2}\sqrt{h} + \frac{1}{4}$, where $h = \frac{(\pi d)^2 n}{\rho}$, comes out less than 5 for most cases, and the formula cannot be applied. The error with wires up to 0·4 mm. must be very small, and currents up to 2·5 amperes can be measured in this way. Prof. Fleming has recently shown † that it is possible to measure larger currents accurately by diminishing the inductance of the heating circuit by suitably spacing the wires. In order to test the behaviour of the junctions in circuits of varying frequency, the readings on a junction of copper and Eureka with a heating wire of Eureka (diameter 0·33 mm.) were compared with the indications of a hot wire instrument on the expansion principle, by Johnson & Phillips. The range of this ammeter was from 0·1—1 ampere, and readings were first taken between these limits with continuous current.

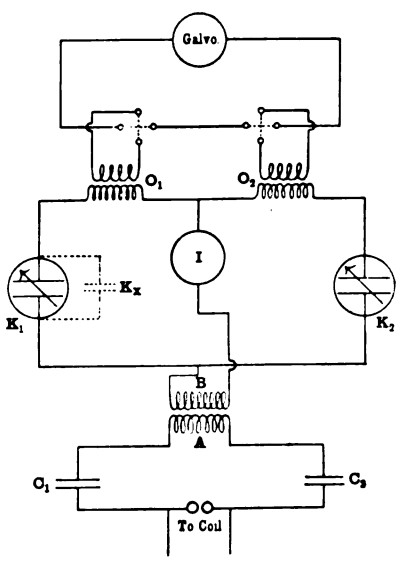


FIG. 7.

The two instruments were then joined in series in a circuit containing a standard inductance and a variable capacity, and the calibration repeated with oscillating currents with frequencies of $2{\cdot}3 \times 10^6$ and $3{\cdot}1 \times 10^6$. The current was varied by changing the length of the spark-gap and the frequencies were measured by means of a Fleming cymometer. The curves in Fig. 6 show the higher readings of the ammeter at the higher frequencies, the maximum error being about 6 per cent. The resistance of the ammeter was 1·11 ohms, and that of the thermo-junction 0·53 ohm, but the most serious defect of the former was its sluggish action. The galvanometer connected to the junction came back to zero in 3 seconds from switching off the maximum current, but the ammeter took 22½ seconds to return under the same circumstances. The calibration of the two instruments was again checked with continuous current after these experiments and found to be unaltered. The uses of the instrument described above may be extended to measurements of magnetising currents of small transformers and the currents in dielectrics, but it has the largest scope in radio-telegraphic experiments where the possibility of rapid variations in sensibility is almost a necessity.

Digitized by Google

Many useful applications can also be made of the differential action of two equally sensitive junctions, and the writer has developed the method shown in Fig. 7, which enables low capacities to be balanced with ease and accuracy. A coil, A, which is in an oscillation circuit with capacities C_1, C_2 forms the primary of an oscillation transformer, the secondary B of which can be moved so as to vary the coupling. Connected to the terminals of B are an indicating instrument, I, and a pair of similar circuits each containing a variable condenser, K_1, K_2, and the primary coil of a small oscillation transformer, O_1, O_2. The secondary coils are in very close coupling and are joined to the terminals of the heating wires of two similar thermo-junctions. The junctions are in opposition and are connected to a sensitive galvanometer. The deflection is reduced to zero by balancing the variable capacities K_1, K_2, and the sensitiveness adjusted by varying the coupling between A and B. The indicating ammeter I shows the value of the current in the main circuit, and experiment will easily show the maximum value that can be reached without burning out the junctions. After noting the readings of the variable capacities, the capacity K_x to be measured is joined in parallel with one of the variable condensers, and this latter varied until the deflection is again reduced to zero. The difference in the readings gives the capacity of the condenser K_x. It is advisable to partially withdraw B before inserting the test condenser in order to avoid overheating the junctions, and in case of differences in the calibrations of the junctions the heating circuits may be exchanged and the mean value taken. This precaution is unnecessary if the inductances of O_1 and O_2 are small, as the process is similar to the double weighing method of eliminating error. In an experiment made by this method, the capacities C_1 and C_2 were Leyden jars with capacities of 0·0012 mfd. each, and the coils A and B were of No. 16 copper wire wound on tubes 6 cm. and 4 cm. in diameter. C_1 and C_2 were moving sector variable air condensers, and the oscillation transformers in the condenser circuits were of No. 16 copper wire—primary eight turns, secondary four turns, one winding over the other. The junctions were of iron and constantan, and a Paul unipivot galvanometer was used. A change of 0·8 per cent. in the capacity was easily detected, and with a reflecting galvanometer this sensitiveness could be considerably increased.

The writer wishes to express his indebtedness to Dr. Drysdale and Mr. Jolley for their encouragement and valuable suggestions.

MAGNETIC AND ELECTRICAL PROPERTIES OF IRON-SILICON ALLOYS.*

BY C. F. BURGESS AND J. ASTON.

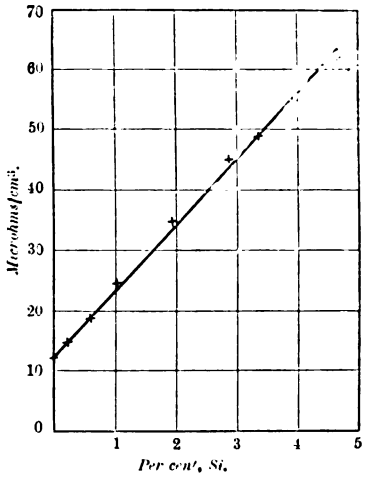
The belief was held for a long time that, as far as magnetic properties were concerned, purification was the method to be looked to for improvement of iron. That this is not true is now, of course, common knowledge. The work of Barrett and Brown, in 1901,† on alloy steels, made by Hadfield, gave for irons with additions of 2¼ per cent. of aluminium or 2½ per cent. of silicon permeabilities excelling those of pure iron; investigations of the authors have shown this same effect by additions of about 2 per cent. of tin or about 4 per cent. of arsenic. It is not probable that the influence of these elements, all non-magnetic, is directly, or in a strict chemical sense, the cause of the marked improvement of magnetic quality. It is more likely that the effect is due indirectly to some change in the physical structure of the iron itself. This supposition is seemingly confirmed by the influence of the heat treatment of high-purity iron. Annealing at lower temperatures (about 700°C.) results in improvement of quality throughout the entire magnetisation curve, due to the removal of all cooling and forging strains; while annealing at the higher temperature of 1,000°C. results in a deterioration of quality in the upper ranges, and a higher permeability at low magnetising forces.

From the above investigations have resulted the present-day materials so largely used in transformer work, in which the percentage of silicon varies from about 3 to 6 per cent. In these silicon steels the heat treatment is of importance comparable with that of the silicon content, and the practice seems to be annealing at high temperatures. The result is a material of very high permeability for the lower magnetising forces; the saturation limit is reached at comparatively low densities, however, and beyond this point the quality is not exceptional. This characteristic makes the steel particularly suited to alternating-current working, where low working densities are the rule. The low hysteresis losses, together with the added benefits of high electrical resistance and slight deterioration due to ageing, are the special features of the silicon steels.

Our investigations covered tests of 15 iron-silicon alloys, with from 0·233 to 4·655 per cent. of silicon. Electrolytic iron of high purity (99·9+) formed the basis of the alloys. All effects noted, therefore, may be ascribed, as far as due to chemical composition, to the added element alone. The results of the tests are given in tables and curves by the authors. Four heat treatments were adopted: Forged, annealed at 675°C., annealed at 1,000°C., and quenched at 900°C. Comparison is made with a standard bar of electrolytic iron of high magnetic quality.

In the unannealed condition all the curves fall considerably below the standard, particularly in the upper ranges; the best results are obtained with bars of lower silicon content, and the lowest with those of highest silicon; but the latter for very low values of H have the highest permeability of the series.

Annealing at 675 deg. raised the maxima of all curves, but the comparative order is about as in the previous condition. Second annealing at the higher temperature of 1,000 deg. resulted in a falling off



ELECTRICAL RESISTANCE OF IRON-SILICON ALLOYS.

of the permeability for the bars of lowest silicon content. But for three bars of highest percentage of silicon (2·83, 3·33 and 4·66 per cent.) there was a considerable improvement of quality at the lower magnetising forces, with but little change for the upper ranges. Here the curves fall below those of lower silicon, and all are well below the standard. Quenching at 900 deg. resulted in a deterioration of quality, particularly in the lower ranges, with but little change at higher magnetising forces.

In general, the coercive forces become less with annealing, and reach a minimum after heating to 1,000 deg. The very low value of 2·7 reached by a bar with Si 4·66 per cent., after annealing at 1,000 deg., confirms the previous deductions of high permeability for this alloy at low magnetising forces.

Summarising, the results of these tests do not show a general improvement of permeability due to the presence of silicon in electrolytic iron, but the experience of practice is confirmed in that a high-silicon alloy after annealing at high temperature is of high permeability for very low magnetising forces and densities such as are used in transformer design. The improvement is not so great in our tests as it is in commercial materials; it may be that the effect of the silicon is more pronounced in the presence of certain impurities or after special heat treatment. For the purpose of comparison, results of tests on commercial silicon steels obtained from steel and electrical manufacturers are given by the authors.

A feature of steels for transformer working, second only to the magnetic quality, is a high electrical resistance, to reduce the eddy current loss. In this respect the silicon steels are an additional advantage. The curve herewith shows the effect of increasing the amount of silicon.

NEW POST OFFICE TELEPHONE EXCHANGE AT GLASGOW.

The telephone system in Glasgow enjoys the distinction of having been the centre of a great controversy and one which raged fiercely for a number of years. With the opening of the new Post Office common battery exchange a fresh epoch is marked in telephone progress in this country. The inauguration of the new service is a fitting climax to the events of the past, and is a matter for all-round congratulation. As far as the past is concerned it is probably best dismissed by the old phrase, "let bygones be bygones." Our friends in the northern capital may now rest content upon the knowledge that their latest telephone achievement is as up-to-date as electrical enterprise can make it, and, further, they have the supreme satisfaction of being in possession of an equipment which is the result of British enterprise and is the product of British labour.

FIG. 1.—NEW POST OFFICE BUILDING, GLASGOW.
The New Telephone Exchange is installed on the second floor, the whole of which it occupies.

The new exchange presents a large number of entirely distinctive features. The first of these is the installation of the entire equipment upon a single floor. This applies to the power plant, test room, subscribers' sections and staff quarters. This convenient arrangement of the equipment is made possible by the ample dimensions of the magnificent new Post Office building in Waterloo-street. The imposing nature of this structure will be gathered from Fig. 1, which is an exterior view of the building, and shows the south and west fronts. The telephone exchange is situated on the second floor, and it will be noticed that there is ample lighting provision made. The position of the pillars supporting the roof allows ample space for the switch sections.

It will be remembered that the call-wire system was adopted some years ago in Glasgow. The object of this system was to do away with indicators, but progress in the design of telephone exchange equipment has proved that the method, while simple in principle, is complicated in practice. It has accordingly come to be regarded as obsolete. This is not to be wondered at, when it is considered that an operator can only deal daily with 40 per cent. of the number of calls which she can handle in a modern exchange. During the busier times of the day special operators had to be put on, and it was not unusual for a messenger to be requisitioned to find and clear a connection which could not be dealt with by any other means. When the Post Office acquired the telephone plant of the Glasgow Corporation it was not unnatural that the call-wire system was abandoned. The new exchange is the first to supersede a portion of the existing call-wire equipment of some 5,000 subscribers' circuit which have been gradually transferred. At the same time the new plant makes provision for an additional 5,000 lines, making a total of 10,000 in all for the exchange just opened.

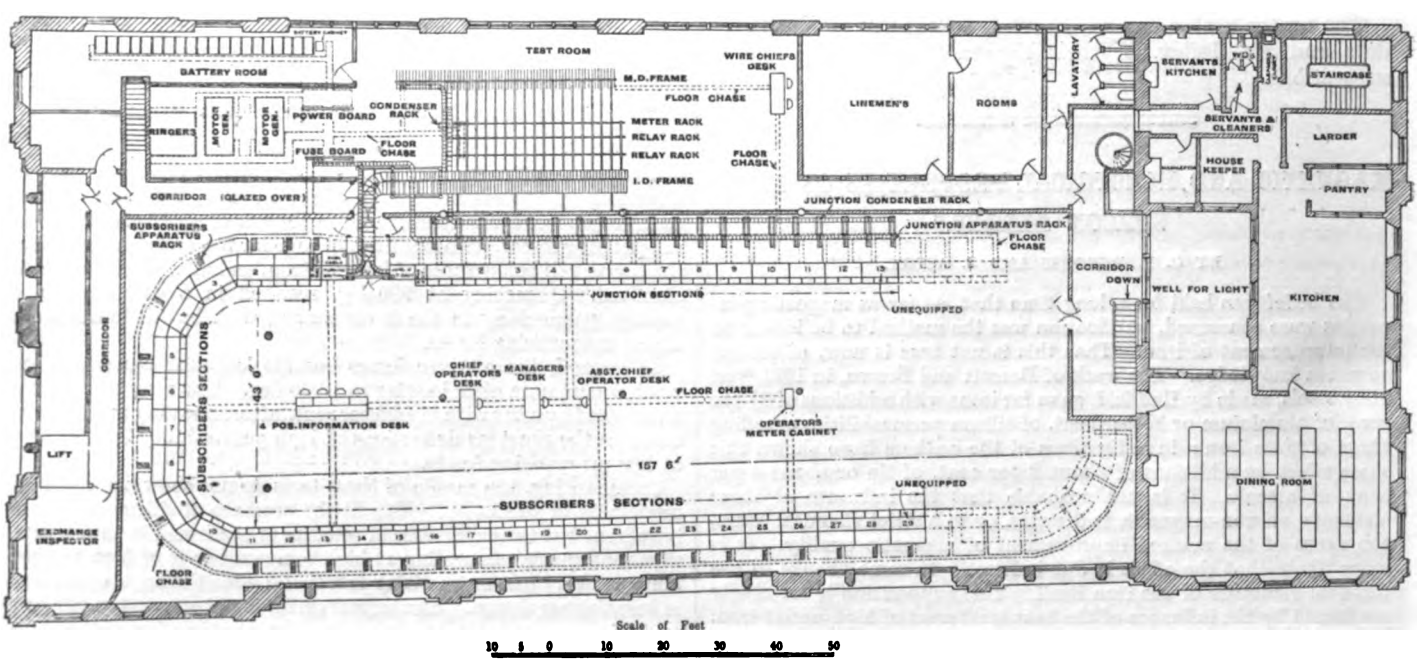

FIG. 2.—FLOOR PLAN—POST OFFICE CENTRAL EXCHANGE, GLASGOW.

Digitized by Google

We have already remarked that the latest equipment is of British design and manufacture. The entire work has been carried out by the Peel-Conner Telephone Works (Ltd.), who made the whole of the apparatus at their Salford factory, and subsequently erected it in the exchange. A general idea of the nature of the undertaking will be gathered from the plan to a 30 kw. generator. These are of standard "Witton" design, and were made at the Birmingham works of the General Electric Co. A general diagram of the power circuits is shown in Fig. 3. In addition to the two main motor generators, there are two ringers belt-driven from motors each of 4 H.P. One of these motors is direct-connected to the 250-volt line of the Cor-

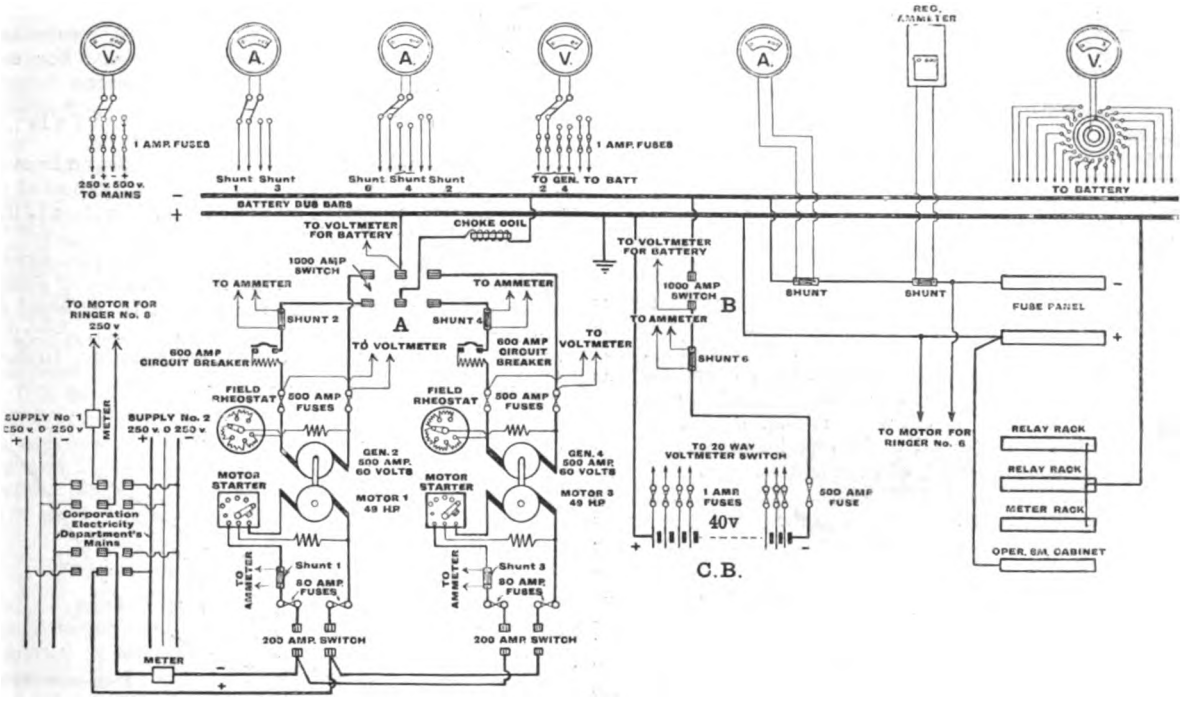

FIG. 3.—GENERAL DIAGRAM OF POWER CIRCUITS IN NEW EXCHANGE.

view of the exchange which is shown in Fig. 2. This serves to illustrate the convenience of placing the whole of the equipment on a single floor. It is particularly noticeable in the position of the power plant, which is immediately adjacent to the switch-room. Usually this portion of the equipment must

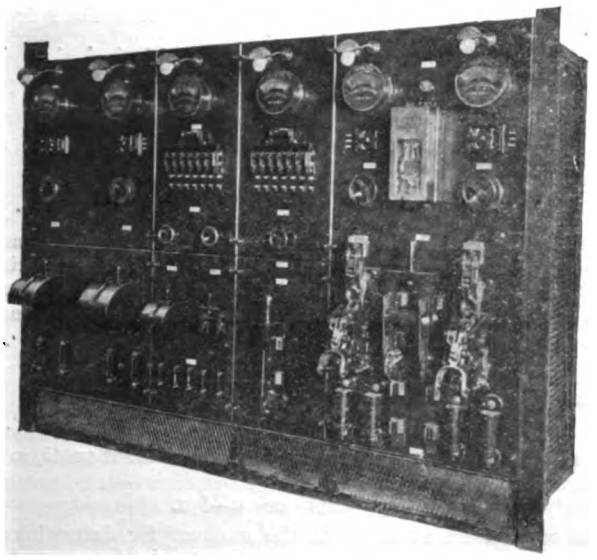

FIG. 4.—GENERAL VIEW OF POWER SWITCHBOARD.

perforce be placed in the basement or in some other position at a considerable distance from the main boards.

For the supply of energy to the exchange two distinct direct current three-wire services have been laid in from the network of the Glasgow Corporation electricity department. From these a supply at 500 volts is given to the motor generators. A switch is provided so that the mains of either service may be coupled to the machines. There are two main motor-generators, each consisting of a 49 H.P. motor direct-coupled

poration service, and the other motor is operated at 40 volts from the 60-volt generator 'bus bars, a choke coil being used to reduce the pressure. The common battery shown at CB on the diagram comprises 20 Chloride cells having an ultimate capacity of 3,230 ampere-hours at a 9-hour discharge rate. The initial equipment of plates provides for a capacity of 2,720 ampere-hours at the same rate. As there are two independent supplies of energy, the battery has not been arranged in duplicate. A 1,000-ampere two-pole double-throw switch, shown at A in the diagram, is provided for connecting either generator to the battery. The battery is protected by a 500-ampere fuse

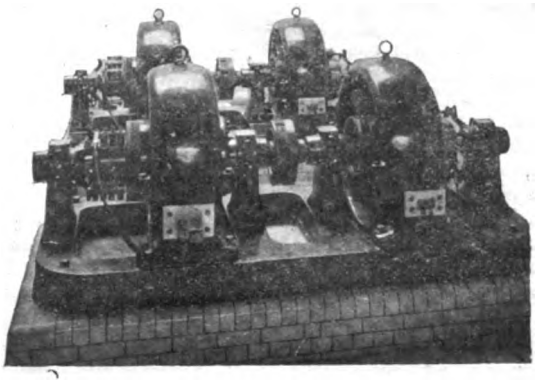

FIG. 5.—WITTON MOTOR GENERATORS INSTALLED IN NEW TELEPHONE EXCHANGE.

enclosed in an air-tight cabinet, and erected near the end cell on the negative pole. The negative battery lead can be disconnected by means of a 1,000 ampere switch shown at B on the diagram. This switch can only be used when the battery is disconnected from service. In this case one of the generators would have been previously coupled up for supplying current direct to the exchange. The power board and motor generators are illustrated in Figs. 4 and 5.

COHERERS.*

BY W. H. ECCLES, D.SC., A.R.C.S.

(*Concluded from p. 727.*)

Summary.—A method of investigating detectors is developed with special reference to the relations between the energy given to the detector in the form of electrical vibrations and the energy delivered by the detector, as direct current, to the circuit of the indicating instrument. The response of the detector was measured by comparing the sound in its telephone with the sound produced in the same telephone by interrupting a measurable direct current. The results of experiments on coherers made of oxidised iron wire dipping into mercury, and on coherers made of a clean iron point touching an oxidised iron plate, are recorded. The author puts forward the hypothesis that the properties of an oxide coherer may arise solely from the temperature variations caused in the minute mass of oxide at the contact by the electrical oscillations and by the applied E.M.F. He examines the hypothesis mathematically and shows that most of the phenomena recorded can in this way be accounted for as perfectly as the present state of the measurements permits.

A Hypothesis of Coherer Action.—The experimental results described above lead me to offer a simple hypothesis of the mode of operation of the class of coherers in question. When an oxidised wire is dipped into mercury or touched against a conductor, the oxide dielectric between the conductors is so thin and so extended that a considerable current, relatively speaking, can be passed through it. The films of oxide used in the experiments had a thickness of the order of a wave-length of light and an electrical resistance usually between 50 and 2,000 ohms. When a current is passed through the film, heat is generated in the film and raises its temperature. The rise of temperature may be considerable if the mass heated is small, but is limited by the escape of heat to the surrounding metal. If the rise of temperature does not affect the resistance of the heated material appreciably, the relation between the applied E.M.F. and the consequent current will be a linear one; but if the resistance of the material varies with its temperature the relation between E.M.F. and current will not be linear. A direct experiment on a film of oxide of iron showed that its resistance coefficient was negative and nearly 1 per cent. per degree Centigrade. Calculation shows that a resistance-temperature coefficient of this magnitude can cause the voltage-current curve to deviate considerably from a straight line. The equation of the curve is deduced below.

If a train of electrical oscillations be passed through the minute mass of oxide traversed by the steady current, its energy appears as heat in the oxide. The resistance falls in consequence, and the equilibrium of the direct current in its circuit is disturbed. Since the rise of current enhances the heating of the oxide, the subsidence of the current to equilibrium is somewhat prolonged when, as in the case of iron-oxide, the resistance-temperature coefficient is negative. Hence the effect on a telephone diaphragm, whose natural period of vibration must be regarded as great in comparison with the duration of a train of oscillations, may be very large. It remains to be seen whether the disturbance of the direct current, caused by a small variation of resistance, can account for the phenomena disclosed in the course of the above-described experiments.

Let W_1 be the fraction of the energy of a single train of oscillations given to the variable resistance ρ of the detector; let $\rho=\rho_0(1-\alpha\theta)$, where ρ_0 is the value of ρ at the temperature of the surroundings. Then $kW_1=(\delta c)c-(\delta\rho)c^2\rho_0\alpha$, where k is a constant involving Joule's equivalent and the specific heat and the mass of the oxide. This initial disturbance $(\delta\rho)$ of resistance is accomplished in less than $\frac{1}{10000}$ second and gives rise to the perturbations of current to be traced immediately.

Let the direct-current circuit of the detector comprise a total invariable resistance r (which includes the resistance of the telephone), the variable resistance ρ of the detector, and the inductance L of the telephone. Let c be the current at any moment and ϵ the applied E.M.F. Assume that the rate of loss of heat from the warmed mass of oxide to its surroundings is $m\theta$, where, as implied above, θ is the temperature of the oxide above the temperature of the surroundings, taken as zero. Then at any time t

$$\frac{d\theta}{dt}=k\rho c^2-m\theta, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and

$$L\frac{dc}{dt}+(r+\rho)c=\epsilon. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Since $\rho=\rho_0(1-\alpha\theta)$, (1) becomes:

$$\frac{d\theta}{dt}+k\rho_0\alpha\cdot\rho c^2+m\rho\cdot m\rho_0. \quad . \quad . \quad . \quad . \quad . \quad . \quad , \quad (1')$$

* Paper read before the Physical Society. A short account of the discussion following the reading of this Paper appeared in THE ELECTRICIAN, April 1, 1910, p. 1021.

The simultaneous equations (1′) and (2) contain the complete history of the fluctuations of c and ρ from any assigned equilibrium condition. We need only investigate here small fluctuations. First, however, let us obtain equilibrium value of c, say c_1, corresponding to a given value of the applied E.M.F. ϵ. Put $dc/dt=0$ and $d\rho/dt=0$ in (1′) and (2) and eliminate ρ. We get

$$\epsilon=\left(\frac{m\rho_0}{m+k\alpha\rho c^2}+r\right)c. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

This equation agrees perfectly with the results of numerous experiments on the iron-oxide-iron coherer. For example, the experimental curve of Fig. 7 has the parameters

$$r=390 \text{ ohms}, \rho_0=970 \text{ ohms}, \frac{k\alpha}{m}=3{\cdot}7\times10^6.$$

In general it would appear that the curves drawn from experiments on detectors should fall into the two classes indicated in Fig. 8 by curves I., III., separated by the case II. In class I. the curve has two vertical tangents; the condition for this is $\rho_0>8r$. If when the coherer is in use the values of ϵ and c pass those corresponding to the lower bend of the curve, the original values of c and ϵ can only be regained by interrupting the current by external agency: the coherer is not "self-decohering." In class III. $\rho_0<8r$: there is no vertical tangent, and the coherer is self-restoring. In case II. $\rho_0=8r$. All these cases can be realised, with patience.

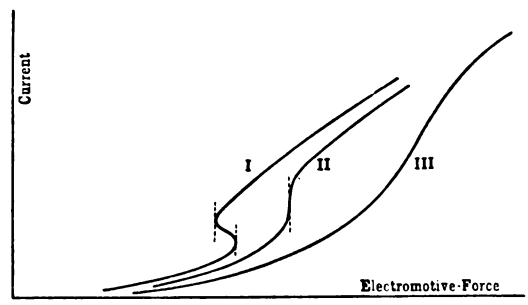

FIG. 8.—IDEAL CURVES SUGGESTED BY THEORY.

To return to the problem of the small fluctuations of the current from its equilibrium value when the arbitrary small variation $(\delta\rho_1)$ is imposed on the system by the arrival of a train of oscillations at the time $t=0$. Equations (1′) and (2) become

$$L\frac{d\delta c_1}{dt}+(r+\rho_1)\delta c_1=-c_1\delta\rho_1 \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and

$$\frac{d\delta\rho_1}{dt}+n\delta\rho_1=-2(n-m)\frac{\rho_1\delta c_1}{c_1}. \quad . \quad . \quad . \quad (5)$$

Here

$$n\equiv k\rho_0\alpha c_1^2+m, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

and ρ_1, c_1 are corresponding equilibrium values of ρ and c.

Equations (4) and (5) give

$$L\frac{d^2\delta\rho_1}{dt^2}+(Ln+r+\rho_1)\frac{d\delta\rho_1}{dt}+\{n(r+\rho_1)-2(n-m)\rho_1\}\delta\rho_1=0, \quad . \quad (7)$$

which can be written in the form

$$[D^2+aD+b]\delta\rho_1=0. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Here a is essentially positive. The quantity b has the same sign as $d\epsilon/dc$, as may be seen by differentiating (3) and comparing (7) and (8). Since my experiments have been for the most part confined to self-restoring coherers, b has been in practice always positive. Thus (8) yields

$$\delta\rho_1=Ae^{-m_1't}+Be^{-m_2't}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

where

$$m_1', {}_2'=\frac{a}{2}\left(1\pm\sqrt{1-\frac{4b}{a^2}}\right).$$

It appears later that a^2 is always much greater than $4b$, so that, approximately,

$$m_1', {}_2'=b/a \quad \text{or} \quad a-b/a.$$

The only datum available at the moment for determining the arbitrary constants A and B in (9) is that the initial value of $\delta\rho_1$ is $(\delta\rho_1)$. Therefore

$$(\delta\rho_1)=A+B. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Using (9) in (4),

$$L\frac{d\delta c_1}{dt}+(r+\rho_1)\delta c_1=-c_1(Ae^{-m_1't}+Be^{-m_2't});$$

whence

$$\delta c_1=-\frac{c_1}{L}\left[A\frac{e^{-m_1't}-e^{-\frac{r+\rho_1}{L}t}}{\frac{r+\rho_1}{L}-m_1'}+B\frac{e^{-m_2't}-e^{-\frac{r+\rho_1}{L}t}}{\frac{r+\rho_1}{L}-m_2'}\right], \quad . \quad (11)$$

which vanishes at $t=0$.

Let the work done in the telephone by the fluctuation of the current through it be w_1, and let the effective resistance of the

Digitized by Google

telephone be P. Thus the rate at which the telephone current is working at any moment is Pc_1^2, and, therefore,

$$w_1 = \delta P \int_0^\infty c_1^2 dt = 2Pc_1 \int_0^\infty \delta c_1 dt.$$

Equation (11) now gives

$$w_1 = -r + \frac{2P}{r+\rho_1} c_1^2 \left\{ \frac{A}{m_1} + \frac{B}{m_2} \right\}$$

$$= -\frac{2P}{r+\rho_1} \cdot \frac{c_1^2}{m_2} \left\{ (\dot{\epsilon}\rho_1) + A\left(\frac{m_2}{m_1} - 1\right) \right\}, \quad . \quad . \quad (12)$$

by using the condition (10).

Now, as stated before, $(\dot{\epsilon}\rho_1) = -k\rho_0 a W_1$, where W_1 is that portion of the energy of a single train of oscillations usefully converted to heat in the detector. Therefore (12) becomes

$$w_1 = \frac{2Pk\rho_0 a}{r+\rho_1} \cdot \frac{c_1^2}{m_2} \left(W_1 - \frac{A}{k\rho_0 a}\left(\frac{m_2}{m_1} - 1\right) \right). \quad . \quad . \quad . \quad (13)$$

The experiments have shown that the term involving the arbitrary constant A is always positive. Hence, if A be positive, m_2 must be greater than m_1; moreover, (10) shows that B must be negative when, as was always the case, $(\dot{\epsilon}\rho_1)$ is negative. These considerations applied to equation (9) imply that $\delta\rho_1$ runs through a series of diminishing negative values, passes through the value zero, and becomes positive. This is not possible. On the other hand, if A be negative, m_2 must be less than m_1, and B may be either positive or negative. If B be positive, (10) shows it must be numerically less than A, and then the condition $m_2 < m_1$ implies that $\delta\rho_1$ in equation (9) changes sign once during its history. Rejecting this case we are left with A and B both negative and $m_2 < m_1$. The quantity m_2 must, therefore, be given the value b/a and m_1 must equal $a - b/a$. Put $A = -f^2$, and (13) becomes

$$w_1 = \frac{2Pk\rho_0 a}{r+\rho_1} \frac{ac_1^2}{b} \left(W_1 - \frac{f^2}{k\rho_0 a}\left(1 - \frac{b}{a^2 - b}\right) \right). \quad . \quad . \quad (14)$$

This equation, regarded as an equation between the energy W_1 spent in the detector and the energy w_1 delivered by the detector to the telephone, is precisely of the form required by the experimental curves of Figs. 4 and 5. Those curves may be regarded, in fact, as determining the constant of integration f^2. The methods of measurement are not yet sufficiently refined, however, to make it worth while to examine this intercept term in detail. The coefficient of W_1, on the other hand, may be profitably enquired into.

In this coefficient P, k, ρ_0, a and r (which includes P, of course) are to be taken as constants, while ρ_1, a, b have values dependent on the square of c_1, the direct steady current passing round the detector circuit. By aid of equations (6), (7) and (8) the part of the coefficient which varies with c_1 may be expressed in terms of the quantity n defined by (6). This quantity n, it should be noticed, is itself a function of the square of c_1, and therefore the following discussion applies equally to positive and negative steady currents through the detector. It will be found that

$$La = Ln^2 + m\rho_0 + rn$$

and

$$Lb = n^2 r - mn\rho_0 + 2m^2\rho_0, \quad . \quad . \quad . \quad . \quad . \quad (15)$$

when, as implied by (3), we remember that

$$m\rho_0 = n\rho_1.$$

Now if (3) be differentiated (15) will be seen to become

$$Lb = n\frac{d\epsilon}{dc}.$$

Hence the coefficient of W_1 in equation (14)

$$\propto (n-m)\left(\frac{Ln}{rn + m\rho_0} + \frac{1}{n}\right)\frac{dc}{d\epsilon}. \quad . \quad . \quad . \quad . \quad (16)$$

It is convenient to think of c_1, the impressed current through the detector, as the independent variable. It is, of course, readily connected with ϵ, the impressed voltage by equation (3) or by Fig. 4.

Then as c_1 is varied the factor $n - m$ has as graph a parabola with its vertex at the origin and with the tangent there horizontal. This parabola rises only slightly within those values of the current ever passed through detectors. The second factor has as graph, when values of c_1 are again taken as abscissæ, a slowly falling curve. As a rule the graph of the product of these two factors appears to be a slowly rising curve. Now the third factor $dc/d\epsilon$ is the gradient of the ϵ, c curves shown in Figs. 7, 8. Hence, for a self-restoring coherer we expect that if we draw curves connecting w and ϵ—that is, the watts in the telephone, and the voltage applied steadily to the detector—we expect to find w rising to a maximum at a value of ϵ rather beyond the steepest part of the steady current ϵ, c curve. This deduction is amply borne out by the experimental curves of Figs. 2 and 6. I am not able at the present moment to enter into an exact numerical examination of the whole matter, but such rough values as have as yet been obtained leave little room for doubt that the quantitative adequacy of the above reasoning is as perfect as its qualitative sufficiency. It may be remarked, in closing, that the term subtracted from W_1 in the bracket of equation (14) has its maximum at about the same value of c_1 as gives the maximum gradient in the ϵ, c curve of the detector. This deduction also has to some extent been experimentally confirmed, but the lability of coherers is so remarkable and the difficulty of carrying a coherer through a variety of experiments without altering its internal state is so great, that full confirmation will only be attained by selection of the best from a very large number of observations.

I have to thank the Royal Society's Government Grant Committee for a grant of money to defray the cost of construction of the apparatus used in the above experiments.

INCANDESCENT LAMPS AS PHOTOMETRIC STANDARDS.*

BY C. H. SHARP AND P. S. MILLAR.

For use as photometric standards well-selected lamps should be employed that have been in service for such a length of time that the change in candle-power at constant voltage throughout a considerable period is inappreciable. In regard to the seasoning of the lamps in any given lamp, when the vacuum character of the surface of the filament and the transparency of the bulb are unaltered, the candle-power depends directly upon the watts expended in it. During the early life of the lamp the watts expended in the lamp at constant voltage change on account of a decrease in the resistance of the filament. When the filament has become stable—that is, when its resistance no longer decreases, the candle-power at constant volts no longer decreases. Now, the measurement of electrical resistance is the most precise, as well as the most convenient, measurement which can be made; the method, therefore, has been adopted to measure the change in resistance of the filament at full voltage rather than the change in candle-power. The total change in resistance of a lamp in the period between its initial and peak-candle-power is, roughly speaking, 0·5 per cent. To obtain a satisfactory determination of the exact point at which the seasoning process should be interrupted, the change in electrical resistance should be measured to something like 1 per cent. or 2 per cent. It is necessary, therefore, that the electrical resistance should be measured accurately to one part in from 10,000 to 20,000. There are two available methods for measuring this resistance change. One is to measure the voltage and current. It is, however, a matter of some difficulty to measure the current through a lamp to one part in 10,000.

For measuring the resistance, use is made of the Wheatstone bridge method, which is easily capable of yielding results to the required precision, and which does not require an absolutely steady applied voltage. In using this method the lamp is connected in series with a manganin rheostat, the resistance of which is approximately equal to that of the lamp when hot, and comparisons are made by means of a sensitive galvanometer. The useful life of an incandescent lamp standard is greatly increased when it is used at constant watts rather than at constant volts.

In most commercial photometric work carbon-filament lamps of the ordinary oval anchored type, standardised whilst rotating, form acceptable standards. For work of higher precision, and for stationary standards in general, use is made of a special type of lamp consisting of two hairpin loops, one within the other, and lying in the same plane. The idea of this form of construction is to render it possible to determine the distance between the photometric centre of the lamp and the photometer screen with the highest degree of precision. In the oval anchored type the different parts of the filament lie at different distances from the photometer screen; hence this distance cannot be determined with high accuracy. The filaments of the parallel filament type of lamp, lying as they do in the same plane at right angles to the axis of the photometer bar, enable the operator to ascertain this distance very exactly. Moreover, in this style of lamp the variation of the candle-power involved in a false adjustment of the lamp, whereby it is not placed with its filaments exactly at right angles to the bar, is very small, and the consequences of a mistake of this kind are minimised.

Ordinarily, in the interests of long life, carbon-filament lamps are standardised at about 4 watts per candle. This involves the disadvantage that the light of the lamp is somewhat redder in hue than that of most of the lamps which are to be compared with it, though this disadvantage is not a very serious one until metal filament lamps are reached. The comparison of a tungsten lamp at 1·25 watts per candle with a carbon lamp at 4 watts per candle involves very great uncertainties on account of colour difference. For this reason there

* Abstract from the "Electrical World" of a Paper read before the New York Section of the Illuminating Engineering Society.

Digitized by Google

has been established a set of tungsten standards, the candle-power of which is known in terms of the carbon standards. The colour difference difficulty, having been met once for all, is eliminated in future work with tungsten lamps by the use of tungsten standards.

A great deal of attention has recently been given to the question of standardising tungsten lamps, since this type of lamp, being very little subject to change in candle-power, would seem to make an ideal standard for the photometering, not only of tungsten lamps, but also carbon lamps. In the latter case the tungsten standards would be standardised at a sufficiently reduced voltage to bring their colour to the right quality. It has been found that the ordinary commercial type of tungsten lamp does not admit of very accurate standardisation. The difficulty seems to be that a variable cooling is introduced by the contacts between the filament and the anchoring wires. To meet this difficulty there has been developed a type of parallel filament tungsten lamp, in which the anchor wires are dispensed with and all variable contacts are removed. This type of lamp is available only for low voltages, but from all indications furnishes a reliable standard. Another type of tungsten lamp standard has been developed, in which the filaments are in the form of straight pieces welded to wires at both the top and the bottom. This plan obviates the variable contacts and enables the construction of lamps for the range of E.M.F. between 100 volts and 130 volts. In precision standards an error of not exceeding 0·1 per cent. is obtainable. In commercial standards the error is kept within 0·25 per cent. The latter degree of accuracy, being greater than is obtained in much commercial photometric work, is sufficient in many cases.

DISCUSSION.

Dr. E. B. Rosa remarked that themethods formerly used for ascertaining when lamps submitted to the Bureau of Standards had not been fully seasoned required observation of the performance of the lamps over a considerable period of time in order to detect any change in the light given by the filaments. At the present time use was made of measuring instruments at least 10 times as sensitive as formerly, and an observer could ascertain within 10 minutes if the lamps were not properly seasoned by noting some change in the resistance of the filament during that period. An idea of the constancy and reliability of incandescent lamp filaments as primary reference photometric standards could be gained from the fact that accurate estimates showed that if well standardised properly seasoned carbon filament lamps were used regularly as reference standards for 100 years the change in light given at a certain wattage at the end of that time would be only a few hundredths of 1 c.p.

PROBLEMS IN POWER TRANSMISSION.*

BY H. W. BUCK.

Summary.—The author discusses the following subjects: The advantages of steel towers, length of span, suspension insulators, anchoring the conductors, the practical limit of pressure, voltage regulation, frequency, lightning arresters and interruptions of supply.

The rise in the price of wood and the reduction in the cost of fabricated structural steel have naturally led to the substitution of steel towers for the old wooden poles on many lines. Such steel construction enables higher supports to be used, and consequently longer spans with resulting economies. Steel supports also eliminate the fire risk. The question of depreciation in a steel tower, due to corrosion, even if galvanised, has, however, not yet been definitely determined, for most tower lines have been in service for only a few years. If the steel legs of the tower are installed directly in the ground it is questionable whether the life of this part of the tower will be any longer than that of a wooden pole. The strength of a tower with its legs in the ground is also uncertain, since the quality of the soil varies to a great extent. If the legs of the towers are concreted in the ground the tower is greatly strengthened and corrosion is practically eliminated, but the cost per tower installed is thereby in some cases as much as doubled. Unless, therefore, the amount of power used in transmission is very large, so that the cost per horse-power of the line is reduced, steel-tower construction is almost prohibitive in cost. In order to reduce this cost it is common practice to make the smaller members of the tower not more than 0·125 in. in thickness. The life of steel members of this small section, even if galvanised, has yet to be determined, although the results on windmill towers are encouraging.

The lengthening of the span on transmission lines has been an obvious result of the introduction of steel towers. It reduces the number of insulators and consequently the opportunity for breakdowns, and has other advantages, but the lengthening of the span has introduced certain difficulties. With the old-fashioned short-span construction common on wooden pole lines the question of sag and strength of conductor was of very little importance. Lines could be installed slack, using soft-drawn conductors, and the strains on insulators and supports could be reduced to a minimum. Conductors on this account seldom broke. The sag was small in any case, and a foot or so more or less made very little difference. With long spans, however, there is a radical difference in requirements. In order to reduce the height of towers, since their cost increases almost as the square of the height, the conductor must be drawn up to the maximum possible tension. This has eliminated the use of soft-drawn metal for conductors and has necessitated the development of commercial hard-drawn copper and aluminium of very high elastic limit. The long span also requires the stringing of the wire with the greatest care with accurate observations as to temperature and tension. The high-working stress in conductors necessary in modern long-span lines has introduced new mechanical problems in insulator joint cross-arm designs. Furthermore, the conductor is stressed so near to its elastic limit at times of low temperature and high wind that a short-circuit on the line is almost certain to burn it enough to cause it to part from a reduction in cross-section. When a conductor does part under these conditions the high initial mechanical tension is likely to cause considerable damage to adjacent insulators, cross-arms, &c., from recoil. A further difficulty in the case of very long spans has resulted from vibration of the conductor and its crystallisation and ultimate breakage at the point of attachment. In such cases it has been found necessary to make the attachment more or less flexible. The suspension type of insulator is specially favourable for this reason. The economical span length for steel construction under present conditions ranges from about 300 ft. as a minimum to 750 ft. maximum, depending upon a large variety of conditions peculiar to each line.

For E.M.F.s up to about 60,000 volts the standard type of pin insulator construction gives very satisfactory results. With the rise in transmission voltage above this figure, however, mechanical difficulties are encountered due to the large size of pin insulator required. The cost of this type of insulator increases nearly as the cube of increase in voltage, above 60,000 volts, and the necessary height of the pin imposes on the cross-arm tensional strains which are objectionable. Probably the most important and radical improvement which has taken place in recent years in energy transmission has been the development and introduction as a commercial success of the so-called suspension insulator construction. It superseded the pin type almost immediately for the very high voltage lines and now is standard for voltages above about 80,000. Its advantages and its successful performance have been definitely established on a number of important transmission systems already in operation. The suspension insulator requires a higher tower than does the equivalent pin insulator. This is a disadvantage, but it is offset by the simplification of the cross-arm possible with the suspension insulator and the elimination of torsion on the arms and head of the tower. The hardware used in connection with the suspension insulators of various forms is not altogether satisfactory, and there is a field for development and improvement here.

Where pin insulators are used the ordinary method of construction consists in drawing the conductor up to tension over the top of the cross-arms or through the groove in the top of the insulator. Since each pin insulator is a fixed point on the line, the conductor when up to tension can be tied in at any insulator and fixed until the next few spans are drawn up, and so on. With suspension insulators the method is not so simple. Usually the wire is slung in snatch-blocks, one hung from each cross-arm and a mile or so of conductors drawn up to tension. The cable is then fixed to some tower with an auxiliary clamp. After this operation it is necessary to transfer the cable from each snatch-block to the suspension clamp on each insulator, and ultimately the auxiliary clamp must be removed. The extra labour involved puts the suspension insulator at a disadvantage in cost of construction. There are possibilities for improvement here, especially in training linemen to this special work, which is new to most of them. Experience is specially necessary for the tying-in of conductors at dead-end insulators where the operation is quite complicated.

There has been considerable discussion as to the best method of securing conductors on suspension insulator lines. Probably the most satisfactory is to place at regular intervals along the line, one mile or so apart, extra strong towers where dead-end insulators can be installed and the line fixed at these points. These towers should be strong enough to withstand any strain likely to occur on the line. The intermediate towers should be equipped with suspension insulators, but with the conductor clamped thereto so that it can slip through in case of breakage. The intermediate towers need then be only just strong enough to carry the actual weight of the conductors and to resist the overturning moment across the line due to wind. At angles, dead-end insulators should, of course, be used with extra strong towers. Italian engineers carried this principle to an extreme

*Abstract of a Paper read before the National Electric Light Association.

Digitized by Google

several years ago by using flexible towers as intermediate supports. The arrangement has special merit in connection with suspension insulators, and has recently been taken up actively in this country. It gives promise of economy, especially from the viewpoint of the cost of tower assembly and erection.

The success with suspension insulators on the recent 100,000-volt lines in this country has been remarkable, and such lines have actually given less insulator trouble than the early 20,000-volt lines when they were first installed. Since the degree of insulation with suspension insulators can be increased to almost any desired extent without involving prohibitive difficulties, there seems to be no reason in the insulator itself why much higher voltages should not give satisfactory results. There are, however, other considerations which will probably limit line E.M.F. to approximately 100,000 volts for some time to come. The insulation of the line itself is a much easier problem than that of transformers, lightning arresters and sub-station equipment, and these devices cannot be considered entirely satisfactory even at 100,000 volts in the present state of the art.

Oil switches become of enormous proportion at this voltage and involve the use of large quantities of oil under conditions where the fire risk is considerable. Furthermore, the spacing necessary between phases at 100,000 volts is so great that sub-station buildings are necessarily very large and expensive. It is questionable whether the economy in conductor cost in raising the voltage from 100,000 volts to 150,000 volts would not be more than offset by the increased cost of insulator towers, sub-stations and operating equipment. There are other problems incident to the very high line voltages which have not yet been solved. The line-charging current is a serious element on long lines even at 100,000 volts, and the atmospheric discharge loss increases rapidly above this voltage. The spacing between conductors for the latter reason will have to be largely increased as the voltage goes up, and it will probably be necessary to increase artificially the diameter of conductor to reduce the discharge loss. This will increase the wind strains on towers and increase their cost. It is provable that 110,000 volts is as high a voltage as is justified on a large commercial scale under the state of the art as it is at the moment. It would be well for electrical engineers to be conservative in this regard in the best interests of permanent advancement, since a too rapid rise in line voltage applied commercially is certain to result in unforeseen difficulties and unsatisfactory service, which can only retard legitimate development.

Voltage regulation under the variable load on very long high voltage lines cannot be considered satisfactory under present conditions. This result is attributable principally to the great inductive drop and the excessive charging current, both of which are exaggerated at 60 cycles. For instance, the wattless leading current in a 100,000-volt 60-cycle single-circuit line 150 miles in length is approximately 50 amperes, or equivalent to 8,650 k.v.a. This requires a very considerable generator equipment to operate the line even at no-load. This charging current magnetises the generator field so that the voltage will automatically build itself up until a condition of high saturation in the generators is reached. In order, therefore, to maintain normal voltage under these conditions the generator direct-current field excitation must be reduced almost to nothing. The combination is highly unstable. As the load comes on, if it is inductive, such as induction motors, the line-charging current may be neutralised or the resultant may actually be a lagging current. The generator fields must then be strengthened to a point which on the no-load saturation curve of the machines would correspond to a voltage much above normal. Assume, then, that some circuit-breaker on the system opens, thereby cutting off a large block of power load and also part of the compensating lagging current; the resultant current at the generators immediately changes from lag to lead, the line-charging current again predominating, and the generator voltage may rise as much as 50 per cent. This serious rise in voltage is caused by momentary speed rise due to reduction in load and armature reaction due to change from lag to lead, and in addition there is the boost of voltage over the line inductance due to the leading current. Other motor users on the system which remain connected to the lines under these conditions will suffer from the disturbance.

This problem in regulation can be solved only by the installation of shunt inductance placed at intervals along the line permanently connected thereto, and so adjusted as to neutralise the line-charging current regardless of conditions in the various receiver circuits. If it becomes necessary to neutralise the lagging currents of the receiver circuits, use should be made of rotary condensers. It is not feasible, however, to neutralise the lagging currents in the receiver circuits with the line-charging current if a good line regulation is required, since one is a constant and the other is a variable.

While a frequency of 60 cycles does not compare favourably with one of 25 cycles for line conditions alone, on account of the increased charging current and inductive drop at the higher frequency, 60 cycles is coming into more general use on the large transmission systems. This result is due somewhat to the necessity of operating in conjunction with existing plants; but there is justification for it in the reduced cost and size of the transformers, which are large and expensive in any case at high voltages. One of the strong arguments formerly used in favour of 25 cycles for transmission is its benefit in rotary converter operation. On account of poor voltage regulation however, it is no longer usual practice to instal converters on long lines, since independent voltage control of the motor-generator set is required. Furthermore, the general adoption of 25 cycles for single-phase railway operation does not look as probable as it did a few years ago; so that greater advantages for overhead work seem to be in the 60-cycle system. Where extensive underground cable networks are involved a frequency of 25 cycles is desirable in order to reduce the cable eddy current and dielectric losses and to lessen the charging current.

Good progress has been made in lightning arresters through the development of the electrolytic type. If a disturbance takes place on a line, thereby causing a wave of high voltage, the electrolytic arrester allows the surge to pass through it satisfactorily and absorbs its energy. Under these conditions current from the generator does not follow and the arrester is not overheated. If, however, the actual voltage on the line rises for reasons previously discusssed, the arrester breaks down and the current in the circuit is actually generator current at the higher voltage, and here the heat generated in the electrolyte is apt to cause an explosion with consequent ejection of liquid, oil, &c., and permanent damage to the disc units.

It is not likely that lightning itself will be as troublesome at 100,000 volts and over as it is on the lower voltages. The insulation of the entire transmission system is so high that the potentials due to lightning are not so likely to cause a puncture, and a point should ultimately be reached where all the apparatus will have sufficient insulation to be practically lightning proof. Arresters are really of use more for protection from so-called surges than from lightning. Even these should be reduced as line voltages increase, since the reaction due to any sudden change in the line current is proportional to the square of the line current. The higher the voltage, of course, the less the current for a given power, so that the tendency should be to lessen disturbances. The steel guard wire installed along the top of many recent transmission lines has given promising results, and the general opinion is that it is a benefit as a protection from lightning. It has an additional mechanical advantage in tying all the towers together and an added electrical use in connecting all the towers so that all must be at the same potential. If it is then necessary to work on a conductor on the line, this conductor can be earthed to any tower and brought thereby to the same potential with every tower, so that work can be safely carried on without danger from shock.

So long as overhead transmission lines exist as they are under the present state of the art, occasional interruptions to service will necessarily occur. It is better to recognise this fact and make provision to reduce the duration of interruption. An interruption once or twice a year, lasting a few minutes, will cause very little inconvenience even to the most exacting public utility. The real problem in satisfactory service is to design switching arrangements and provide spare circuits and apparatus so that when trouble does occur it can be located rapidly, isolated and service resumed at once. Resumption of service should never wait upon repairs.

One of the most important elements in case of trouble is effective telephonic communication between the various parts of the transmission system. The practice lately has been to remove telephone wires entirely from transmission towers, so that they will not be subject to trouble from the high-tension conductors. This arrangement is especially necessary on the very high-voltage lines because of static induction. The latter is more difficult to eliminate satisfactorily than is magnetic induction, which can usually be overcome by transposition.

The largest field for future evolution in energy transmission is toward high-voltage direct current. Its advantages over alternating current from the standpoint of the line itself would be very great. The effective voltage would coincide with the maximum, and the insulator problem would be reduced by 30 per cent. The number of conductors would be reduced to at most two, and possibly one with earthed return would be satisfactory. Line-charging current and self-induction would cease to exist, and the question of power-factor would be eliminated. The whole problem of energy transmission would be vastly simplified, and costs for construction would be reduced. Such a development would undoubtedly double the practicable transmission distance. The problem is not one in energy transmission but one in electromagnetic machinery, and it would involve radical developments and probably some new discoveries. The complications now necessary for the generation and utilisation of high-voltage direct current are such that its general adoption would not be commercially practicable.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free,
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardt. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-second issue of the Supplement is published (Gratis) with the current number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,086 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

THE IDEAL ELECTRIC LIGHT.

What constitutes the ideal electric light is largely a matter of opinion. There are many sides to the question, efficiency being the one that is seldom overlooked. But economy is not the only thing to be aimed at; the colour of the light and its even diffusion are equally of importance. Daylight is usually regarded as the natural standard by which colour and diffusion should be judged; but in both respects the standard so set up is purely arbitrary. It is, indeed, conceivable that, in so far as the effects on the human eye are concerned, daylight may have too much red or blue; in other words, a light of a different character ought not necessarily to be put out of court if its physiological effects on the brain alone are considered. The mercury arc lamp is extremely efficient, in the sense in which the word is used in engineering circles; it is also said by those who have used it to be very pleasant to work by. No complaints have ever been made, in so far as we are aware, of any injurious effect that has been produced by it on the human eyesight, though it has been in continuous use in certain places for lengthened periods. Yet the character of this light, spectroscopically considered, is notoriously different from that of daylight, which seems to show that the arbitrary spectroscopic standard of daylight may, perhaps, admit of a good deal of variation, when looked at from the physiological point of view, without ill effects.

We publish in this issue an abstract of the report by Prof. WEDDING, of Charlottenburg, on the Moore light, and this

Digitized by Google

is probably the first independent statement that has been made on the subject as the result of careful photometric tests. The pertinacity with which Mr. McFarlan Moore has laboured during the 15 years he has devoted to the development of his idea is worthy of all praise. The outside man has, however, to examine the result in the light of cold reason. The obvious fact must be admitted that the diffusion produced by the source of light is in many respects an advance, which could only be produced with other illuminants by the use of frosted globes or by inverting the lamp, or otherwise hiding in one of many ways the source from which the light directly proceeds. Using the word "efficiency" in the usual sense, the light is inferior in this respect to others at present in common use, though for many purposes this would not be held to be a deciding issue. In spite of all the special pleading that has been heard from time to time, we cannot say that the difficulties connected with the installation itself have been altogether disposed of; in fact, we fear that the more we come to close quarters the less will these things loom in the distance like so many unconsidered trifles to be easily overcome. The immense voltage to be applied to the tube through a transformer can scarcely be regarded as a trifle, even by the most optimistic householder; the "glass-plumbing" that has to be undertaken in case of a fracture or repair will need the development of a new type of workman, and make the cost of repairs very serious at any distance from headquarters; the light itself is indivisible, which means that the whole of a room or hall must be lighted, and not a corner that might meet the needs of the case; some sort of a stand-by seems necessary in case of a breakdown, meaning that the installation must be duplicated in some way; the power factor is not likely to be much higher than 65 per cent., so that the lamp is likely to receive rather a cold welcome from the central station engineer; added to this, little or nothing seems publicly known as to the cost of installation, although a good deal of work has been done in America, a country in which the arts of advertisement are not lost on either buyer or seller, and must be taken into account in pioneer installations of this kind, where cost is not altogether a final factor.

Taking these as the most serious items in the case that can be made out against the lamp, the main thing urged on the other side is with regard to the nature of the illumination and the colour of the light. On neither point do we feel altogether convinced. A well-diffused light is not unknown to electrical engineers, and this, too, with a reasonable efficiency. As to the colour of the light, this, of course, depends on the nature of the gas through which the discharge passes. Nitrogen seems to be the usual gas, though with carbon dioxide a whiter light, more nearly approximating to daylight, can be produced at a lower efficiency. Taking the nitrogen light, the colour is described as warm and rosy, and this agrees with previous reports, which described the light as containing a considerable excess of red. It may be of a pleasant colour, but it is certainly different from daylight. The carbon dioxide lamp has been used in places where the matching of colours is an important part of the day's work; but we do not hear the same of the nitrogen tube, which seems to be the commercial article. Prof. Wedding says nothing about the flicker, which has been noticed with ordinary frequencies, such as 60. With a frequency of this order, there has been noticed by other observers to be a well-marked flicker, which produces strange effects when things exposed to the light are moved rapidly to and fro. Users of the lamp are said not to complain of this, and it may be that one easily gets accustomed to it.

On the whole, we are far from rivalling the phosphorescence of the firefly. Not more than 10 per cent. of the power put into the most efficient illuminant with which we are acquainted is turned into light; usually we have to be content with about 2 or 3 per cent. Still, we cannot help feeling that Mr. Moore has quite unconsciously taken up arms against a sea of troubles, an unequal form of struggle at best. He has successfully grappled with the problem of keeping the vacuum constant, or at any rate he has discovered a workable solution. But whether his persistence will overcome the dogged obstinacy of the human mind, which is only too willing to bear the ills it has, remains to be seen.

REVIEWS.

(Copies of the undermentioned works can be had from The Electrician Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

The Gas, Petrol and Oil Engine. By Dugald Clerk. Vol. I. (London: Longmans, Green & Co.) Pp. ix. + 313. 4s. 6d. net.

For now nearly 30 years the name of Dugald Clerk has been permanently associated with the development of the gas engine, not only from the practical side, but also from the interest which he has taken in the elucidation of many difficult problems that have been brought to light by the study of the internal combustion engine.

Any work by this distinguished authority will only be too eagerly read by the student, and all those interested in the development of power. The work in question was published many years ago, and Clerk has now brought it up to the most recent knowledge on the subject. It may be said at once that those who already have a familiar knowledge of the internal combustion engine will find a great deal of modern and interesting information in the work. Those, however, who are approaching the subject as pure learners, and who have not got a knowledge of gas engine practice, such, for example, as the multitude of engineers who are now being educated in the various technological centres, will, we fear, find this work far from easy to master. It labours under the disadvantage of so many recent works on applied science that the logical order of the subject, which is so important to the student, is not strictly followed. The subject matter is all there, and is well treated, but the subjects do not lead from one to another in the order in which the student can most readily assimilate the information. We venture to suggest that those proposing to write technological works which will appeal to seekers of information—and these, after all, are by far the largest class of readers—would do well to study such standard text-books as those of Rankine, Cotterill and Ewing, in which the subject matter is presented in a form suitable for the student to follow readily the various steps.

Clerk adheres in the body of his work to the standard cycles based on air as a working medium (specific heat being assumed as constant), no doubt being largely influenced by the committee of the Institution of Civil Engineers, who after weighing the subject decided, for the sake of simplicity, to recommend as a standard an engine working on a simple fluid like air, and ignoring all the evidence that has been accumulated on the variability of the specific heat with temperature.

The experiments of Holborn and Henning in 1907 proved beyond all question that the specific heat of the permanent

Digitized by Google

gases varies with the temperature, according to linear law, and that further, both water vapour and carbon dioxide follow a law which is still more complicated than the linear form. It is, of course, quite open to suppose that experiments conducted at the high temperatures of 1,400°C. are subject to serious error, and that therefore the absolute values of Holborn and Henning may be uncertain, but we venture to suggest that no treatment of the internal combustion engine may be considered as at all satisfactory which does not take into account the variability of the specific heat.

The phenomena of afterburning, or what is termed "Nachbrunen," have given rise to much speculation as to what takes place during the expansion curve of an internal combustion engine. Clerk himself has long been an advocate of the theory of disassociation, that is, that chemical combination does not take place at the very high temperatures, and that the carbon and hydrogen atoms may exist uncombined in an atmosphere of free oxygen. Other authorities have considered that it is possible for the wall action to account for the apparent contradiction of the raising of the expansion curve above the adiabatic. If, however, the variability of the specific heat be admitted, the whole of these phenomena are most readily explained, as it will be found that the true form of the adiabatic curve as compared with the expansion curve is always above, and never below. We ourselves have plotted a large number of expansion curves in combination with the true adiabatic, taking for the specific heat of the gases the values of Holborn and Henning, Holborn and Austin, and the still later results of Millard and Le Chetalier, the latter of which are admittedly incorrect.

It will be found that during expansion the charge behaves as a perfect gas, and that there is a loss of heat. Moreover, if the heat additions be calculated up to the point of maximum temperature, the whole heat of the charge will be approximately accounted for, a result pointed out in the first instance by Slaby. These experiments, although made as far back as 1887, are still full of information.

In conclusion, we would strongly recommend all those interested in the internal combustion engine to read this work. If they are careful to take out from the vast mass of information which it contains that which is useful they will profit; but we would wish that Clerk had had sufficient time and inclination to re-write the work entirely, and to put before his readers exactly what is his own opinion as regards the phenomena which take place. F. W. BURSTALL.

Finanzierung und Rentabilität deutscher Strassenbahnen. By Dr. FR. HERMES. (Jena: Gustav Fischer.) Pp. vi.+63. M.2·50.

Although the present volume deals exclusively with German tramway finance, it contains a great deal of information which will prove very interesting reading to managers of English tramway undertakings. The subject is well presented and scientifically treated. Only company controlled tramways are considered, municipal undertakings being excluded.

In the introductory portion the author gives a brief but interesting survey of the growth of electric traction in Germany. Chapter I. deals with the question of electrification, and contains remarks on the various groups of interested parties, the electrical companies, trusts, the financial dependence of tramways and divided guarantees. In Chapter II. the author discusses the considerations underlying the granting of tramway concessions, the influence of the town on the length of the line and the tramway fares, the taxes to be paid to the town and their basis of computation, and the length of the term of the concession. Several examples are cited. Chapter III. details the methods of raising capital, which is further examined in Chapters IV. and V. Chapter VI. is on revenue (receipts, fares, competition, expenses, &c.). A large amount of statistical data is also given in tabular form at the end of the book.

The Protection of Railroads from Overhead Transmission Line Crossings. By F. F. FOWLE. (New York: D. Van Nostrand Co.) Pp. vi.+68. $1·50.

The present little volume is the publication in book form of a Paper prepared by the author for the twenty-seventh Annual Convention of the Association of Railway Telegraph Superintendents at Montreal, June 24 to 26, 1908, and deals exclusively with the methods of protecting railroad property and the lives of railway employés at overhead crossings of high-tension lines. The subject is an important one, and deserves the close attention of all engaged in high-tension transmission work. The principles involved are carefully explained, and the protective devices in use are critically examined. It is a book which distinctly fills a gap in the literature of this branch of electrical engineering, and should prove of value. A special feature of the book is the number of excellent illustrations it contains of high-tension lines, which show in a very striking manner the effects of failures which commonly occur in actual practice.

The book starts with an exposition of the dangers consequent upon the use of high potentials and the effects of failure at a railroad crossing; examples of line construction and actual cases of failure are given. The screen protection is next explained, and several types of screen construction are illustrated. The method is restrictive rather than preventive, and for this reason the author does not favour it except as a last resort. Bridge and catenary type of reinforced crossings are also explained and criticised, and underground crossings are considered. Under the heading "Discussion of Proposed Type of Crossing," the points which are vital in drawing up a specification are given, crossings are classified according to voltage, and sleet load, wind pressure, temperatures and factors of safety are considered, together with structures, foundations, insulators, conductors, distance apart of conductors, dead ending and tying, ground cables and low-voltage circuits on the high-tension line. A typical crossing for a high-tension line carrying two 22,000-volt three-phase circuits is then fully illustrated, and a number of useful references are given to the transactions of the American Institute of Electrical Engineers on the subject. In conclusion, we feel sure that a book dealing with the whole subject of high-tension protection by the author would be welcomed by the engineering profession.

LOCATION OF FAULTS IN UNDERGROUND HIGH-TENSION CABLES.*

BY W. A. DURGIN.

Summary.—The author discusses the methods of fault location adopted on the high-tension underground cable system of the Commonwealth Edison Co. of Chicago. A special slide-wire bridge designed for Murray and Varley loop tests is described.

Prompt location by test requires that each terminus of high-tension lines should be provided with a device for short-circuiting the phases of a faulty cable. For a three-phase line, three short lengths of flexible cable, joined at one end and provided at the other with spring clips adapted to clamping the phase terminals firmly, answer admirably. The addition of a longer cable from the common junction increases the usefulness of the device by making a convenient arrangement for earthing, which is further facilitated by installing a permanent earth wire with wing-nut connectors near each cable terminus. A 100 to 200 volt source of direct current should also be available at each terminus. With these devices available, fault location by test resolves itself into four main divisions: (*a*) Analysis of original fault; (*b*) reduction of fault resistance; (*c*) approximate location by predictive tests; (*d*) final location by exploration tests.

Much time may be saved and many errors avoided in predicting locations by analysing the original fault thoroughly. A sensitive voltmeter, a lead from one side of the direct-current source with a lamp socket in series, and some form of bridge for measuring resistances from 0·1 to 300 ohms, are all the apparatus necessary in addition to that noted above. The voltmeter is used to measure insulation resistance by the well-known series method, and should preferably have a resistance of at least 500 ohms per volt, although satisfactory results can generally be obtained with instruments of 200 ohms per volt. The procedure is as follows:—

1. With both ends of all phases clear, measure the insulation of each phase by reading the deflection of the voltmeter when one terminal is connected to the phase conductor and the other to the unearthed side of the direct-current source through a 32 c.p. lamp. If E_2 = voltmeter deflection, E_1 = pressure of direct-current source, R = voltmeter resistance, then insulation resistance = $R(E_1 - E_2)/E_2$.

* Abstract from the "Electric Railway Journal" of a Paper read before the National Electric Light Association.

Digitized by Google

2. If a fault on either phase has low resistance, apply the lead from the lamp directly to this phase, and if the lamp glows measure the fault resistance with the bridge, reverse the battery and re-measure, taking the mean of the two bridge measurements as the true resistance.

3. Test for crosses between such phases as show the same insulation by earthing one and re-measuring the insulation of the other, using first the voltmeter and then, if a low cross exists, the bridge.

4. Have the short-circuiting device applied at the distant end of the line, caution being used to make firm low-resistance contacts on all phases.

5. Measure the resistance of all uncrossed loops with the bridge, checking the result against the resistance computed from the known size and length of line.

6. If either loop shows high resistance, determine the insulation on the far side of the "open" over a clear phase, and unless that is much lower than the insulation on the test side of the "open" proceed with No. 7.

7. Measure the insulation of the test side of the open phase when the far side is earthed over a clear phase, thus getting a minimum limit for the resistance of the path across the "open." If in No. 6 the insulation resistance of the far side is low, No. 7 is practically covered by No. 6.

8. If all the loops show "open," check continuity by having the short-circuiting device earthed at the distant end of the line and applying the voltmeter to each phase. If one phase is then shown continuous and has fair insulation, apply No. 7 to the other two phases.

This procedure gives a clear picture of fault conditions. If the analysis shows all faults or crosses of more than 100 ohms resistance, the next step is to reduce one to this or preferably to a lower magnitude. The apparatus for "breaking down" faults depends largely on the size of the system concerned. In any system, pressures from twice that of the normal transmission to a few volts, and current of at least 5 amperes, will be required at the fault, while for long lines excess current capacity must be provided to supply charging current at the higher pressures. When special apparatus is to be provided for a moderate-sized system, the most satisfactory results will probably be obtained from a single-phase testing transformer of ample capacity supplied from the regular low-tension system and controlled through a water rheostat. Provision should be made for following fault conditions with ammeter, voltmeter and wattmeter connected to the transformer, and for quickly checking the fault resistance at frequent intervals during the reduction process by series direct-current voltmeter readings.

The procedure in this reduction process varies with the conditions at the fault. The object is always to carbonise a sufficient amount of paper to carry a current of 1 ampere to 2 amperes for several hours, as it is practically impossible to produce any form of metallic path from sheath to conductor in the presence of paper. If the paper at the fault is dry, a current of 1 ampere continued for 5 to 10 minutes will generally produce a carbon path of less than 10 ohms resistance, which is stable for currents of a few amperes; but with damp paper a 3 to 5 ampere current is required for about 10 minutes for drying, followed by a 1 ampere current for five minutes for carbonising. With a fault submerged in water, no manipulation will produce carbonisation. These fault conditions can frequently be deduced from the behaviour of the voltmeter and ammeter. Thus a submerged fault has a resistance to direct current of from 1,000 ohms to 3,000 ohms, and requires 2,000 volts for any alternating current from 1 to 5 amperes. Furthermore, the frequent interruption of the arc at the fault by water gives both meters a peculiar kicking swing. A similar swing is also observed at first with a damp fault, but lessens perceptibly after one or two minutes; and when the arc is once established, the pressure required rapidly diminishes. With a dry fault very little swinging occurs, and if the current is held constant the pressure drops very rapidly to zero. The lower the resistance produced the easier it will be to make accurate locations, but, unless the reduction is carried below 100 ohms, a 1,000 ohm fault is nearly as satisfactory as one of intermediate resistance. It is important to work always on a single-phase or loop, for if two or more phases are earthed, or more than one cross exists, a successful exploration test depends on reducing the resistance of one fault much below that of the others, and, on the other hand, a successful predictive test depends on preserving the unfaulted phases intact for use as normal standards.

Resistance forms the basis of most predictive tests, for this quantity is easily measured to an accuracy of one-tenth of 1 per cent., and proportionality to length is approximately realised. Of the many resistance methods only two are generally applicable to power cables—the Murray and the Varley loop tests. Both these tests are special applications of the Wheatstone bridge principle, and in consequence a modified bridge is required. The essential features can be shown by describing the apparatus illustrated in Fig. 1, which, although apparently crude, has been found to answer all requirements. This consists of a slide wire, C-SL, mounted over a paper scale divided into 100 parts, numbered in two ways, the inner scale 0-100-0 and the outer 0-50-100. Between SL and the posts LL, 5 and 20 are mounted three coils, the first having a resistance exactly equal to the slide wire (about 0·75 ohms), and the second and third 5 ohms and 20 ohms respectively. The key K serves to control the connection between the binding post E and the chisel blade P, which is used as contact on the slide wire. Connections to the cable under test are made through 6 ft. lengths of large flexible leads, equipped with clamps capable of gripping firmly any form of switch part which may serve as the cable terminal; the resistance of these leads in terms of equivalent lengths of the various sized cable conductors is tabulated for use in correcting measurements. A portable galvanometer, having a resistance of about 30 ohms and a sensibility of 0·4 millivolt per division, and a box containing eight dry battery cells, complete the equipment.

The resistance to be measured is connected between posts 20 and C, the galvanometer between posts SL and C, and two or three cells of battery between posts 20 and E. The point of zero galvanometer deflection is found with P on the slide wire, when, if S = reading on the outer scale, the resistance equals $20S/(100-S)$ ohms. If the resistance is less than 7 ohms, the connections are transferred to post 5 from post 20 and the measurement repeated, 5 ohms being substituted for 20 in the formula. In practice, the values of $20S/(100-S)$ and $5S/(100-S)$ are plotted against S in the form of curves, so that resistances are read off directly for any given value of S. For values between 0·1 and 200 ohms the apparatus gives sufficient accuracy to check the continuity of conductors or to provide the data for a Varley loop location. The loop tests are applicable only when the faulted conductor is continuous—that is, when its resistance from terminus to terminus is entirely unaffected by the fault, and when at least one unfaulted conductor is available in the same or a parallel cable. For either test, the phase which has the lowest resistance fault is joined to a clear conductor at the distant terminus with the short-circuiting device described above, using every precaution to make the connection of negligible resistance to insulate it well from the ground.

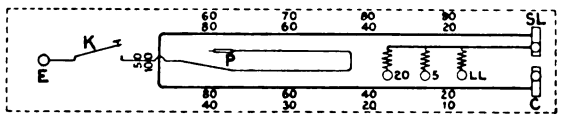

FIG. 1.—SIMPLIFIED SLIDE WIRE BRIDGE.

In the Murray loop test the two ends of the cable loop thus formed are then connected to the ends of the slide wire at the posts SL and C, the galvanometer also being connected between these posts. When an "earth" is to be located, the lead from the earthed direct-current source used for insulation measurements with the 32 c.p. lamp still in series is connected to post E, and the point of balance is found with P. If the galvanometer is not sufficiently sensitive, a second 32 c.p. lamp may be connected in parallel with the first, care being taken to make and break contact at K rather than P. If S = slide wire reading on inner scale expressed as decimal part of 1·00, L = cable length = equivalent length of single connecting lead from slide wire to cable terminus, then $S(L+1)-1$ = distance of fault from testing end of cable. A check measurement is next made by reversing the connections of the cables when the point of balance is found on the opposite side of the slide wire, and a second check by transferring connections from post SL to post LL. With this latter connection the slide wire is one-half of the measuring loop, and S is read on the outer scale with twice the precision of the former measurements. No check reversal can be made with this connection, as the faulted phase must be connected to C in order that the balance point may fall on the slide wire. The mean of the three measurements is taken as the Murray loop location.

The standard Varley loop test differs from the Murray loop merely in using a fixed ratio for the balance arms of the bridge, represented by the slide wire, and in inserting between one end of the balance arms and the faulted side of the cable loop a variable resistance which is adjusted until zero galvanometer deflection is obtained—that is, until the inserted resistance plus the resistance of the cable up to the fault bears the same ratio to the resistance of the remainder of the cable loop as one balance arm of the bridge bears to the other. The true Varley test cannot be made with the slide wire bridge, but a modification which combines features of both loop tests can be performed by connecting the cable loop between posts 5 and C—the faulted side to 5—with galvanometer between posts SL and C. This

Digitized by Google
LIBRARY OF THE UNIVERSITY OF CALIFORNIA

places the 5 ohm coil in series with the faulted side of loop, and leads to a new point of balance on the slide wire. Then, if S = slide wire reading on outer scale expressed as decimal part of 1·00, Lr = resistance of one conductor of cable, lr = resistance of one connecting lead from slide wire to cable terminus (2Lr + 2lr = resistance measured by loop bridge), and X = location of fault in per cent. of cable length from testing end; then

$$X = \frac{(2Lr + lr) - S(5{\cdot}00 + 2Lr + 2lr)}{Lr}.$$

It has been assumed throughout that the faulted cable is made up of a single-sized conductor, and that a clear phase in this cable is used to complete the loop. If, however, the line is composed of known lengths of different sized conductors, or if a clear conductor of known length and size in a parallel cable is used, it is only necessary to remember that the percentage length obtained by either test is in reality a percentage of total resistance and to make the necessary computations to reduce this resistance measurement to percentage length.

The procedure has been outlined as applying to an "earth" fault, but the only change necessary to adapt it to the location of crosses is to treat one of the crossed conductors as "earth," connecting the direct-current source between it and the contact blade of bridge, the other conductor being considered the faulted phase.

The essential points in any satisfactory exploration test are to produce a large difference in some electrical condition on the near and far sides of the fault, and to provide a detector which shall only be affected by this condition. With sheaths bonded at frequent intervals to prevent electrolysis, the path of a signalling current from an "earth" to the sending station will divide first at the fault and further subdivide at each bonding point. A similar effect will result, even though the sheath is unbonded, if the duct line is damp or any other form of distributed earth connection exists. Hence, a continually diminishing portion of current will return over the sheath toward the sending station, while another continually diminishing

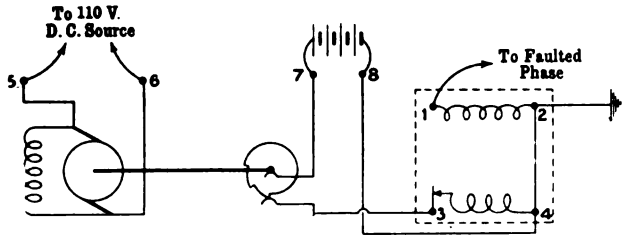

Fig. 2.—Vibrating Interrupter.

portion will continue along the sheath to more distant bonds. Any detector, therefore, which responds equally well to current flowing in a conductor or in the sheath will continue to indicate beyond the fault until the point is passed, where the last trace of signalling current leaves the sheath. Furthermore, any detector which responds at all to sheath currents will give most confusing signals due to railway and other stray currents.

These considerations lead to the development of a longitudinal exploring coil to be used with a telephone receiver. When the magnetic circuit of the coil is parallel to the axis of the sheath, and the winding, therefore, at right angles thereto, no effect is produced by sheath currents alone, but with conductors spiraled as in all high-tension cables a loud signal is produced by current flowing over the loop circuit formed by the conductor up to the fault and the sheath back toward the sending station. When the fault resistance can be reduced to a few ohms, so that currents of 8 and 10 amperes can be produced with a 115 volt direct-current source, very satisfactory signals may be obtained by using such a current sharply interrupted from 50 to 100 times a minute. Any form of "flasher" is adapted to the purpose, which gives a quick break and is capable of operating with certainty for a sufficient period to permit the exploration of the entire length of the longest line should location by the explorer method alone be necessary. In many cases, however, it is extremely difficult to reduce the fault resistance below 50 or 100 ohms, and in some instances even when so reduced the "earth" quickly burns off under currents of more than 2 or 3 amperes.

Such conditions are well met by an interrupting vibrator. This, as shown in Fig. 2, consists of a small 110 volt shunt wound motor, which, through reduction gearing, drives a three-point cam switch controlling the battery connection to the primary of an induction coil. The vibrating spring of the coil breaks contact about 200 times a second, and as the cam switch makes irregularly spaced interruptions of the vibration increase, the words "Hur-ry—up," repeated once a second, result. These irregularly spaced interruptions of the vibration increase the life of the vibrator contacts and battery, and give a distinctive signal. With eight dry cells connected to the primary, currents from 0·4 to 0·2 amperes can be forced through resistances from 0 to 100 ohms. Direct currents of this magnitude interrupted at low frequencies produce no sensible sound in the detecting apparatus, but the exploring coil and receiver are so much more sensitive to high-frequency currents that the signal from the 0·2 ampere current of the vibrating interrupter is quite as loud as that which would be obtained from a 15 ampere "flasher" current.

The sensitiveness of the explorer and receiver are such that with high-frequency currents the displacement of the conductor due to spiraling is sufficient to cause a signal when the explorer is parallel to the sheath axis, even though the sheath carries no return current. For complete silence the explorer must be absolutely parallel to the conductor axis, and, when used on a cable, to the sheath axis as well. This condition may be attained by connecting the vibrator between earth and all cable conductors in parallel. Charging current then flows out over all conductors, but as these are disposed symmetrically about the cable axis the combined effect is strictly equivalent to that of charging current flowing along a single straight conductor at the centre, the sheath also being equivalent to such a central conductor. The signal from charging current, then, is entirely eliminated by adjusting the explorer accurately along the cable axis, if the charging currents are approximately equal for all phases. Such approximate equality will exist unless the resistance of the faulted phase up to the fault is a considerable percentage of the fault resistance—that is, in general power work—unless the fault resistance is less than about 10 ohms. As no interference from charging current is experienced with the single-conductor connection on very low resistance faults, the entire range from 0 to 100 ohms is covered by using the multiple-conductor connection from 100 to 10 ohms, and the single-conductor connection below 10 ohms.

THE PRACTICAL CONDUCTANCE OF ELECTROLYTES.*

BY J. W. RICHARDS AND W. S. LANDIS.

Under the above title is discussed the actual conductance of the electrolyte in electrolytic refining tanks as they are ordinarily set up and operated. In almost all refining tanks the edges of the anode and cathode plates, usually of the same size, are at some distance from the sides and bottom of the tanks. The free space, that not directly included between the plates, is a field through which stray current flows, the current lines being usually curved. It adds considerably to the conductance of the electrolyte. The authors have endeavoured to measure experimentally the conductance of these lateral or bottom prisms of electrolyte in order to see to what extent they influence the conductance of the electrolyte as a whole.

The experimental method used was to place two electrodes of pure copper in a neutral copper sulphate solution against the ends of a glass cell which they completely covered. Readings of current and voltage allowed the calculation of the conductance of the cell as a whole to be arrived at, repeated readings being taken at different values of current and voltage until accurate values were obtained for the conductance. The plates were then raised by intervals of 1 cm. and the conductance of the cell determined each time as before. From the conductance of the cell as a whole, as thus measured at each interval of rise, was subtracted the calculated conductance of the prism of electrolyte directly between the plates, thus leaving the conductance of the bottom prism. The conductance of the bottom prism was then compared with its full calculated conductance, and the percentage which the former formed of the latter recorded. Similar experiments were made with cells of different dimensions. It was found that while the conductance of the bottom prism was different for different lengths between the plates, its percentage conductance as calculated above was practically constant for any given ratio of depth of solution under the plates to length of solution between the plates. We have therefore plotted from our most reliable experiment the percentage conductance of prisms below the plates, taking as ordinates the ratio of depth to length and as abscissas the percentage conductance as calculated above. (*See* Fig.)

For zero ratio the conductance is, of course, 100 per cent., and for an infinite ratio 0. An interesting observation is that for a given conductance between the plates the actual (not percentage) conductance of the prism below the plates reaches a maximum at a finite increase in depth, and thereafter remains constant. In several of our experiments this maximum conductance was reached with a ratio of depth to length of approximately 0·8.

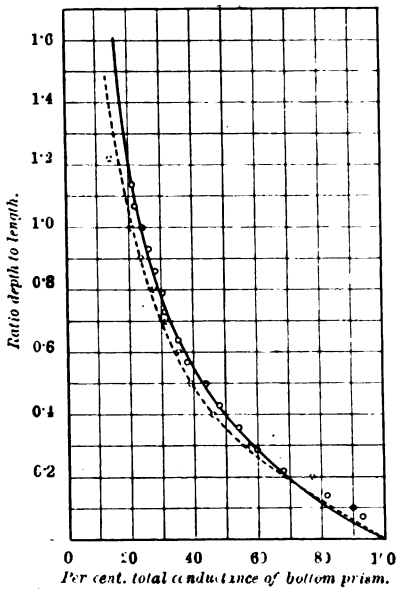
In order to determine whether the conductivity (specific conductance) of the electrolyte affected the values determined as above,

*Abstract of a Paper read before the American Electrochemical Society.

Digitized by Google

the authors tested electrolytes of widely varying conductivity with approximately identical results, and furthermore tested sheets of copper tinfoil and zinc; the most careful experiments being made with zinc and the ratio determined from it practically duplicated the ratio obtained from the copper sulphate electrolyte. The results obtained with zinc are shown by the dotted curve.

In cells in which the electrode covered only a portion of the ends we also attempted to determine the conductance of the prism of electrolyte not directly underneath the electrodes, but to one side, and which may be assumed as having connection with the electrodes only at their corners. In making these determinations, electrodes were used smaller than the ends of the cells and were also raised up by successive centimetres, leaving besides the prism directly between the plates, the side prism between the edges of the plates and the side of the tank, the bottom prism between the bottom edges of the plates and the bottom of the tank and the diagonal bottom prism. The conductance of the cell as a whole being measured for each successive withdrawal of the plates, the sum of the calculated conductances of these prisms, between the electrodes, at the side of the electrodes, and directly under the electrodes, was subtracted from the measured conductance of the whole cell in order to determine the residual conductance ascribable to the bottom diagonal prism. The number of factors to be considered in this measurement left the determination of the conductance of this bottom diagonal prism rather unsatisfactory. From three or four carefully conducted experiments, however, it can reasonably be concluded that the conductance of a relatively large diagonal prism, such as would be encountered in practice, does not appear to add sensibly to the conductance of the cell as a whole.



There results from this study the conclusion that the practical conductance of the electrolyte situated between the two electrodes (including that directly, laterally and beneath the electrodes) can be calculated by adding to the conductance of the portion between the plates the virtual conductances of the side and bottom prisms. These latter are to be determined in each case by calculating from the respective total conductances of the prisms (as if between parallel plates) and the use of the percentage conductance as given in the curve herewith. It is necessary to reckon the ratio of depth (distance from edge of plate to side or bottom of tank) to length (distance between the plates), refer to the curve and find for this ratio the percentage of the total conductance of each prism actually available. The conductance of the diagonal bottom prism may be neglected in all cases in actual practice.

For practical purposes, where the ratio of depth to length happens to be greater than 0·8, the conductance of the prism of electrolyte beneath or alongside the electrodes may be considered as constant, and calculated as equal to the total conductance (between parallel end plates) of a prism of electrolyte of the length concerned and one-quarter as deep as it is long. Or, in other words, the maximum conductance of these lateral or bottom prisms of electrolyte is reached when their depth (measured away from the plates) is over 0·8 of their length (distance between the plates), and may be calculated as the total conductance of a prism of solution whose depth is one-quarter of its length.

There are various other more complex problems in this connection, particularly in tanks used in electro-plating where the plates are not against the ends of the tank, or between uneven surfaced electrodes, but the infinite variety of such cases makes a satisfactory study of them impossible. We have worked out the simplest case such as we think will assist the electrochemical engineer in the design of ordinary metal refining tanks.

The fact that there is reached a maximum conductance after a given depth, holding for both electrolytes and metals, is important as showing the uselessness of increasing the depth of the electrolyte underneath or at the sides of the electrodes past a certain point, such increase in dimensions adding nothing to the conductance. The uselessness of increasing the depth (width) of an electrical metallic conductor conducting between points of contact at the two ends on the same side, beyond a certain depth which is approximately the ratio of depth to length of 0·8, is quite as important for the electrical engineer in the design of equalising bars and heavy bus bars of short lengths, and shows the great importance of making contact over the whole end or face of the conductor in order to get the full utilisation of the metal contained in it. Connection should never be made simply along an edge or at the corners.

CORRESPONDENCE.

THE ASSOCIATION OF CONSULTING ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will the Association of Consulting Engineers be a truly representative body if its membership is to be confined to "those who are corporate members of the Institution of Civil Engineers?" There must be a number of consulting engineers, thoroughly competent in their own speciality, who would be excluded by this restriction; and it is open to question whether they or the new Association would be the poorer for their exclusion.

Certainly in some special lines of work, as, for example, telephony, the man who has spent his life in the work is better qualified than the average corporate member of the Civils.

It is to be hoped that in justice to those who for a variety of reasons have not been able to join the Civils the proposed restrictions will not be maintained.—I am, &c.,

Westminster, August 15. HERBERT LAWS WEBB.

[We comment upon this letter in the Editorial Notes.—ED. *E.*]

THEORY OF THE QUADRANT ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The usual formulæ, as well as those given by Mr. Beattie in your current issue, express the sensibility in terms of the *absolute* potential of the needle. Now this has always seemed to me to be unreasonable, for the absolute potential is a mere mathematical convention, useful enough in its proper place, but a thing whose value can never be known. It is also my opinion that the common use of this function in connection with the electrometer leads to confusion of thought and hides the real actions.

The forces acting in an electrometer do *not* depend on the absolute potential of the vane by itself, as generally stated, but on the *difference* between that potential and that of the quadrants. Essentially, an electrometer consists of a condenser having one, or both, coatings movable, and forces act on the parts in such a way that any motion they produce increases the capacity. For a given position these forces are proportional to the square of the potential difference between the two coatings; for a given P.D. and different positions they are proportional to the increase of capacity per unit displacement. If the vane be surrounded by several conductors at different potentials, each system must be worked out by itself and the resultant of their several effects found. The potential of the instrument relative to earth is only of importance when earthed bodies have an effective capacity with the vane.

Thus, a quadrant electrometer has two fixed systems, pulling the vane in opposite ways, since the capacity of one is increased and that of the other diminished by any motion. If the

Digitized by Google

potentials of the quadrants be V_1 and V_2, while that of the vane is V_v, then

The torque due to the first is $\frac{1}{2}\frac{dc_1}{d\theta}(V_v-V_1)^2$.

That due to the second is $\frac{1}{2}\frac{dc_2}{d\theta}(V_v-V_2)^2$.

And the total torque is $\frac{1}{2}\frac{dc_1}{d\theta}(V_v-V_1)^2+\frac{1}{2}\frac{dc_2}{d\theta}(V_v-V_2)^2$, or

$$k\vartheta=\frac{dc_1}{d\theta}(V_2-V_1)\left\{V_v-\frac{(V_1+V_2)}{2}\right\}+\left(\frac{dc_1}{d\theta}+\frac{dc_2}{d\theta}\right)(V_v-V_2)^2.$$

Hence,

$$\frac{\theta}{(V_2-V_1)}=\frac{\frac{dc_1}{d\theta}\left\{V_v-\frac{(V_1+V_2)}{2}\right\}}{k-\left\{\left(\frac{dc_1}{d\theta}+\frac{dc_2}{d\theta}\right)\Big/\theta\right\}(V_v-V_2)^2}.$$

If we have perfect symmetry, which requires the central part of the periphery of the vane to be circular and concentric with the suspension, and also that the needle shall be narrow enough and the quadrants wide enough to make the edge effects negligible, then $\frac{dc_1}{d\theta}=-\frac{dc_2}{d\theta}$ and we get the usual formula; but it ought to be retained in the form showing differences of potentials. If the symmetry be not perfect, the relation between the two parts of the deflecting couple due to the electrostatic forces may be anything at all according to the shape of the vane and its position relative to the quadrants. For example, the Nalder "Ohmer" is a quadrant electrometer having no mechanical control, but in which the vane is able to find a position in which the one part of the couple balances the other; this position depends on the ratios of the two P.D.s, and not on their actual values, which is the necessary condition for an ohmmeter.

Mr. Beattie's division of the total electrostatic couple into a controlling and a deflecting couple is a little unfortunate, and his assumptions that the former part is independent of the potentials of the quadrants and proportional to the displacement, quite unjustifiable. Its variation with the displacement is usually erratic.

The highest curve of Fig. 4 corresponds to an increase of the total capacity being produced by a deflection, while the lowest is for the case in which the total capacity is diminished. The exact shape of these curves, however, will depend on the rates of increase of capacity, and the net rate of increase is not usually proportional to the capacity.—I am, &c.,

THE ELECTRIC PROPULSION OF SHIPS.*

BY ATHOLL BLAIR AND J. F. WILSON, B.SC.

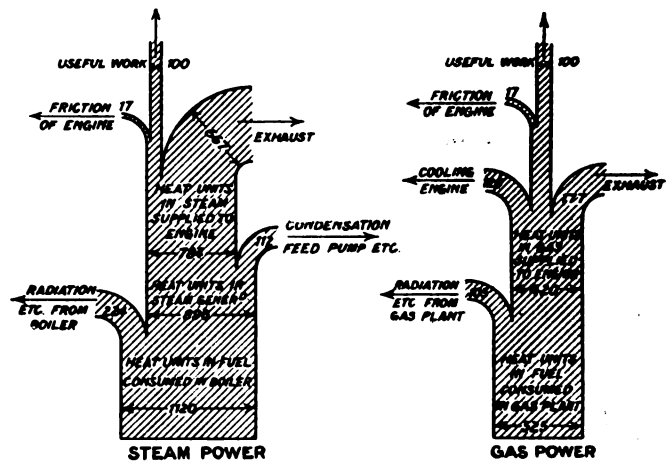
Summary.—The authors consider a cross-Channel vessel, the s.s. "Londonderry," and give particulars of the suggested equipment for electrical propulsion. Suction gas plant is proposed for generating current for the electrically-driven auxiliaries, whilst high-speed turbines would be employed for the main generators. Details of the equipment are given.

The authors here propose to take an actual vessel, to consider the equipment best suited for electrical propulsion, and to compare the suggested scheme with the vessel as at present equipped. For this purpose their choice has fallen on the Midland Railway Co.'s steamer "Londonderry." Several reasons led to this choice. In the first place, the authors have full particulars of this vessel; secondly, it is a vessel with steam turbines of modern design; and thirdly, anything pertaining to local affairs should arouse more attention.

The details of the s.s. "Londonderry" are as follows: Length 330 ft., breadth 42 ft., depth 25½ ft. There are two double-ended boilers 22 ft. long and 11½ ft. diameter, and one single-ended boiler 11½ ft. long and 11½ ft. diameter. The total heating surface is 12,500 sq. ft., and grate area 400 sq. ft., whilst the working pressure is 150 lb. per square inch. Forced draught on the closed stokehold system is fitted, the fans for this purpose being driven by direct-current electric motors. There are three turbines—one high pressure and two low pressure—driving three shafts, with a three-bladed propeller to each. With the low-pressure turbines, operating the wing shafts, are incorporated the reversing turbines, which run in vacuo when not in use. Complete condensing plant is installed. All the propellers are 5 ft. diameter and 4½ ft. pitch. The speed of the central shaft is 750 revs. per min., and of the wing shafts 670 revs. per min. The power developed is about 6,300 shaft horse-power at a speed of 21 knots. A mechanical efficiency for the turbines of 92 per cent. gives 6,850 I.H.P.

The steam turbine is in several ways an ideal motor, for it has few working parts, and, above all, gives a uniform torque; its outstanding feature, however, is that it becomes more efficient the higher the speed. Now we know the screw propeller to be most efficient at low speeds, and the question is how to utilise both most efficiently. Various mechanical gear boxes of ingenious design have been suggested, but electrical methods only are considered here. By adopting such a system we are enabled to run our steam turbines at a much higher speed than what would be desirable where they are coupled direct to the propeller shaft, and so to obtain a saving in turbine weight as well as an economy in steam consumption.

We have met with a number of suggestions much to be admired, but we have not yet seen any system, carried out in detail for any particular vessel that would comply with actual conditions. We cannot couple to the propeller shaft a motor of large diameter that will enable the propeller shaft to be at a feasible depth below the water surface; neither can we place our motor far aft, and thus economise in shafting, for the lines of the vessel will not allow of it.



* FIG. 1.—HEAT EFFICIENCY DIAGRAMS 250 B.H.P.

Hence we see the engine room will be situated in much the same position as it is at present. It is our intention to drive all auxiliary machinery by electric motors, including all pumps, hoists, capstans and steering engines. In the "Londonderry" the forced draught is motor driven, and in her sister ship, the s.s. "Manxman," motor steering gear is employed, whilst there is not any one element in the whole ship for which we cannot substitute an existing motor-driven machine.

Suction Gas Plant for Auxiliary Power.—We propose to generate our supply for the lighting and all auxiliaries by a single prime mover, with a duplicate set as a standby. For this we have full confidence in putting forward the claims of suction gas plant, coupled with a three-phase generator. Our reasons for adopting the gas plant are twofold. In the first place, we can vary our load in a few minutes to suit the conditions and yet maintain its full efficiency; and, secondly, we can show it is one of the cheapest and most economical prime movers applicable to such a case. The power taken by the auxiliaries is rarely correctly estimated. The lengthy steam pipes to winches and steering engines, giving rise to great radiation and condensation, account for losses far greater than the average chief engineer would admit. We have fixed upon a set of 250 B.H.P., which is about 4 per cent. of the total power of the main engines. As to the relative efficiency of suction gas and steam plants, we have selected a heat unit diagram of efficiency in both cases (*see* Fig. 1*), representing up-to-date practice. We see that the suction gas plant is twice as efficient as the steam plant. As to the distribution of power to the auxiliaries, in the case of the "Londonderry" each auxiliary element is driven direct by its own steam engine, and we

* Abstract of a Paper read before the Belfast Association of Engineers.

* Fig. 1 is reproduced from "Producer Gas" (Dowson and Larter), by permission of Messrs. Longmans, Green & Co.

Digitized by Google

may gather at once that the over-all efficiency of the auxiliary engines is not to be compared with a single steam unit of equal power. To balance against this, there is a loss in the electrical transmission and generation in the suction gas plant amounting to about 25 per cent., whereas in the distribution for the steam plant there would, under very favourable conditions, be a loss of 50 per cent. The efficiency of the coupled motors would be about the same as the existing efficiency of each auxiliary engine. Hence, again, we have a balance in favour of the gas plant of 25 per cent. Thus we may sum up the over-all gain as 50 per cent. for consumption and 25 per cent. for distribution.

The whole producer plant would occupy just the same space as the single-ended boiler and the turbo lighting set installed on the "Londonderry." The weight of the over-all gas plant would be very approximately the same as the existing steam plant. The conditions vary so much that no hard and fast rule could be laid down, nor could we make a direct comparison, as no data exist. The same remark applies to costs, it only being a question of going into detail of such designs of sizes of auxiliaries to suit the requirements of the "Londonderry." To be on the safe side, we will content ourselves with an extra 10 per cent. cost in the gas plant installation, an outlay that would be fully recovered by the saving in consumption in the first 12 months.

The Electrical Proposal.—Direct-current working is outclassed at once on account of sparking difficulties; in fact, at the present day, direct-current machinery is only adaptable to comparatively small work. So far it has been found impossible to construct a direct-current turbo-generator of over 2,000 kw. capacity, whilst turbo-alternators of large power are quite common. Another point, and really the main consideration, is that the minimum price for direct-current turbo sets is 18s. per kilowatt, compared with 13s. per kilowatt for alternating-current sets for any capacity up to 1,500 kw.

In regard to the motor, the size required is in the neighbourhood of 3,000 H.P. (one motor on each shaft, twin screw). Anything of the nature of a rubbing surface carrying such a large power would be a tremendous drawback on board ship, so that we may consider continuous current out of the question, both from the generator and the motor point of view. Turning our attention to the alternating-current side, we find the induction motor would suit our purpose very well. It has one drawback over its direct-current rival. It exhibits its best properties at a high speed; but, as we shall see later, we can afford to sacrifice a few per cent. in efficiency, and in a ship the main point is simplicity of construction. We have two main types of induction motor. Hitherto we have favoured the type having a wound rotor and slip-rings in preference to the squirrel-cage rotor. The reason for this preference is primarily that the slip-ring motor can start up against load by introducing resistances into the rotor circuit, and we may control its speed by the same device. For a large motor this would entail the same troubles as in our direct-current motor. In the squirrel-cage motor, however, note the compactness, durability, ease of repair, great mechanical strength, ease with which it gets rid of heat, practically constant speed and low cost.

The authors next describe the three-phase system of supply and the operation of a three-phase motor. As pointed out, however, the squirrel-cage armature has one fault which has not made it a favourite in land work. It starts badly against a load. Now one of the beauties of ship propulsion is that the motor is not required to start against a load—*i.e.*, the torque or turning effort at starting on the propeller is just the resistance to churning of the water, and once the motor has got a start it has no difficulty in reaching its full speed. To show what can be done in starting and running large squirrel-cage motors, we may instance the Simplon Tunnel locomotives. The motors, of which there are two, are three-phase squirrel cage, with pole changing devices on the stator. The difficulty of starting torque is overcome by starting with the winding of 16 poles, then changing over to 12 poles, then to 8, and finally to six poles. The pole-changing devices are operated pneumatically, and the rotor winding is constructed of thick copper tubing. The starting current necessarily raises the temperature of the rotor, and this reaches 492°F. In consequence, the stator windings are completely enclosed to prevent radiation from the rotor. This was also required because of the extremes of temperature (in winter on the north side the temperature is sometimes 13°F., while the southern half is 82°F.). The air is full of water vapour, consequently the locomotives emerge dripping wet. The rotor is cooled by allowing air to pass right through it. It must be agreed that such a motor is eminently suitable for marine work.

To return to our own case, we require to run our turbine at a high speed for the sake of economy. Our motor, however, is limited to a rotor diameter of 7 ft. At first we worked out a design, on the particulars given of 1,500 revs. per min. for the turbines and 180 for the shafts, and found ourselves confronted with the following difficulties: If we advocated, for the sake of a good generator design, a four-pole machine, that meant we must adopt 50 cycles. Hobart has shown that a 25 cycle, two-pole 1,500 revs. per min. turbo-generator is almost as heavy as a 25 cycle four-pole 750 revs. per min. machine, so that there is much to be gained by keeping the cycles high. This is borne out by S. P. Thompson's data, given in his Howard Lectures on "High-speed Electric Machines." There you will find only 117 watts are available from a cubic inch of active material in the two-pole 1,500 revs. per min. machine, while a four-pole 1,500 revs. per min. machine would provide from 212 to 288 watts, or more than double the output per cubic inch.

Now in regard to the motor. As we said, the dimensions of the vessel limit our rotor diameter to 7 ft., and this with the motor in the engine room. Placed aft, to save three lengths of shafting, this would mean reducing the diameter to 4 ft. A frequency of 24 cycles would mean 16 poles on the motor, and 48 cycles 32 poles, for 180 revs. per min. With an available circumference of 22 ft. this would mean that the poles would be so inconveniently near to one another in the 32 pole machine that it would result in a poor electrical design. With 3,000 H.P. and a diameter of 7 ft., even with 16 poles and frequency 24, such a long armature ($5\frac{1}{4}$ ft.) makes the power factor 0·9; whilst 32 poles and a frequency of 48 brings it down to under 0·85—*i.e.*, produces an increase in current of at least 15 per cent., and a consequent increased heating loss of 32 per cent., an increase over the 16 pole design of 11 per cent. Therefore there is much to be gained by keeping the cycles low and raising the speed of the motor. This accounts for us compromising between the two requirements and fixing upon a propeller speed of 300 revs. per min. The motor will, therefore, have 16 poles and the generator 4, with speeds of 300 and 1,200 revs. per min. respectively.

So far we do not think that anyone has gone seriously into the matter of the design of these motors and turbines, but all with one accord are struggling for devices to give a variable speed. In the present case, with the cross-Channel boat, this seems unnecessary, as the speed may be controlled for running out and in port, where economy does not particularly concerns us, by adjusting the speed of the turbine. Throughout its entire range—or at least as far down in speed as we wish to go—a 1,200 revs. per min. turbo and 300 revs. per min. shaft will give a 4 to 1 gear ratio.

In this country there have been two main systems proposed to overcome this difficulty of obtaining variable speed on the alternating current motor without wasting power. As to Mavor's system, in which a spinner is employed, Mr. Durtnall has pointed out that such a combination is not only liable to mechanical troubles, but the rotor is really the driving element. This means that the outside of the spinner and the stator are occupying most valuable space on board ship. The rotor would have to be of small diameter and long, making a most inefficient motor. Again, the drawback to the Paragon system* (of Mr. Durtnall) obviously lies in the excessive diameter of the motor to get a suitable design for the large number of poles. Another point is that the four-pole generator has to be large enough to supply the motor when running at lowest speed, and yet on the other speeds it is only required to produce the fields—*i.e.*, it is practically running idle. A breakdown on the four-pole machine would also stop the ship.

A more reasonable scheme to obtain a large reduction ratio would seem to be to adopt a similar arrangement to Ziehl's double-field generator, which also uses the idea of the revolving field produced by three-phase currents. Let the revolving field of such a rotor be supplied as in the Durtnall scheme, but this time from a separate small rotary converter; then run up the turbine to twice the speed of this field, but in the opposite direction. The field will thus be equivalent to one travelling in the same direction as the shaft, but with only half the speed—*i.e.*, we get a generator which gives us half the frequency that the ordinary type would give us for the same speed and the same number of poles. The three stator terminals of the motor would then be connected direct to the turbine generator terminals, and both starting and intermediate speeds would be obtained by running between half speed and full speed of turbine, on the stop valves of the turbine itself.

Last year a new motor, called the Hunt Cascade motor, manufactured by the Sandycroft Foundry Co., appeared. This may prove the solution of our difficulty. The arrangement is similar to the ordinary induction motor—a short-circuited rotor without slip-rings, but with a double winding. From published tests it seems that greatly increased power factors are obtained at remarkably low speeds, using high frequencies.

If the maximum economy on intermediate speeds was required,

* Described by the authors in their Paper. A four pole (excited by a small generator) and a 12 pole machine are assumed on the turbo shaft, and a 60 pole induction motor on the propeller shaft.

Digitized by Google

then recourse must be had to the windings mentioned in the Simplon Tunnel equipment. Suppose that two equal sized turbo-generators be put in to supply the 3,000 H.P. to each motor independently, and that one of these turbo-generators broke down, then the windings of the motors could be rearranged for half speed, and the two motors run in parallel off the other turbo. As, however, the total power is reduced to one-eighth at half vessel speed, this turbo would only run at one-quarter load or thereabouts. Now, if we introduced some arrangement to get four-fifths speed out of the motor the power used

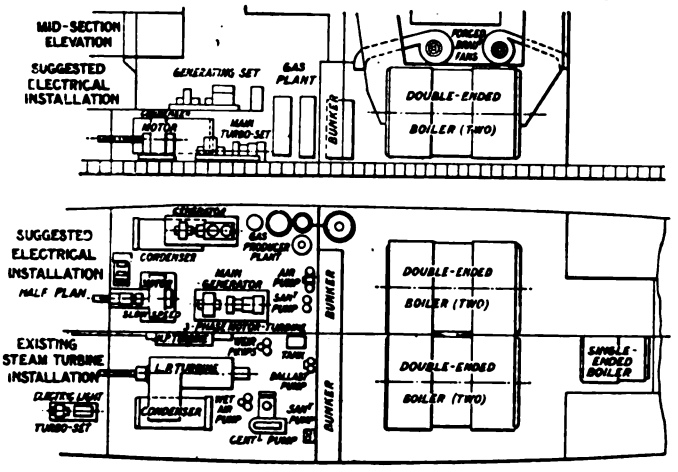


FIG. 2.—DIAGRAM SHOWING THE PROPOSED LAY-OUT OF S.S. "LONDONDERRY," AND THE EXISTING INSTALLATION.

would be approximately reduced to one-half, and one set would do it economically. Such an arrangement can only be obtained by a double winding, such as a 16 pole on top speed and 20 pole at four-fifths speed. This would be more costly, but it would perhaps pay for itself, as it would form a stand-by in the event of a winding breaking down.

There has been much discussion in the Press on the question of voltage. If we consider for a moment existing voltages on board ship, the Board of Trade would not permit more than 250 volts. Such a pressure would mean an enormous current; the cables would have to be very large to keep down the heating losses, and the designs would also be unworkable. If these schemes are to come into operation, the Board of Trade would raise their limit, and allow at least 2,000 volts. As this pressure is now quite common ashore, and the cables are to be confined to a short length in the engine room, there would be no risk.

The sizes of the electrical plant may then be summarised as follows:—

Turbo-generators.—Two sets of 2,400 kw. four-pole machines, 40 frequency and speed 1,200 revs. per min., 2,000 volts, 800 amperes per phase at a power factor 0·9, steam pressure at stop valve 150 lb. per square inch, 100°F. superheat, consumption 11 lb. of steam per indicated horse-power-hour, weight of turbine, generator and bed-plate complete 30 tons each set. Rotor diameter 3 ft. 9 in., length 3 ft. 4 in., external diameter of stator 5 ft. 6 in., efficiency of generator 96 per cent.

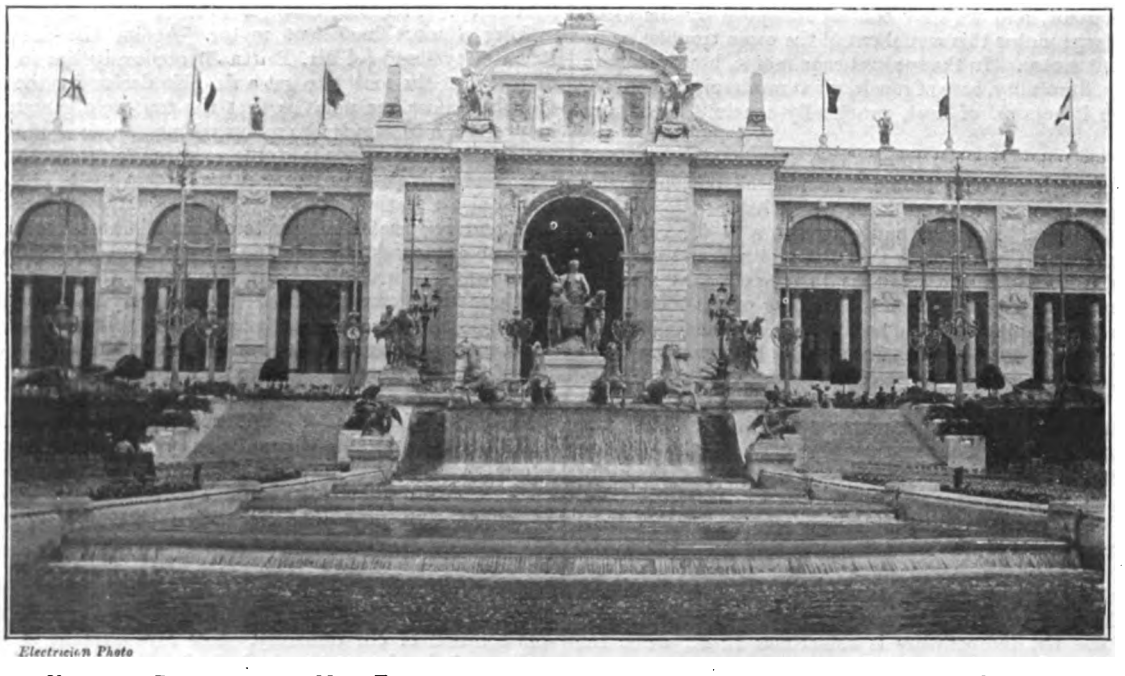
Propeller Motors.—Two 2,870 B.H.P. three-phase 16 pole 40 frequency at 300 revs. per min., 96 per cent. efficiency at power factor of 0·9, rotor diameter 6 ft. 3 in., and length 4 ft., external diameter of stator 8 ft. Weight of each motor, with thrust block complete, 35 tons.*

Fig. 2 shows the proposed arrangement and the existing installation.

The authors finally give figures of the estimated results with the electric drive, but were unable to state the actual cost figures for the s.s. "Londonderry" with the existing installation, so that the saving by adopting the electric drive could not be put forward.

DISASTROUS FIRE AT THE BRUSSELS EXHIBITION.

On the 14th inst. a fire broke out in the Belgian section of the Brussels Exhibition, and owing to the flimsy nature of the buildings it spread so rapidly that in a few hours practically the whole of the Belgian, British, French and Italian portions were gutted. The daily papers have dealt very fully with the fire, so that our readers will be well acquainted with the main details. In accordance with the custom now prevailing of reporting all large conflagrations, the cause of the fire was attributed to an electrical source, but, strangely enough, these rumours have not been accepted with the usual avidity, except, of course, by the gas journals, and the majority of the daily papers have refrained from definitely attaching blame to the electrical installation. Reports received at the moment of going to press give an emphatic denial to these early rumours, but the matter is being sifted by the authorities, and, we understand, particularly by the British Commissioner, Mr. U. F. Wintour, and his staff. We extend our sympathies to Mr. Wintour and to his assistants for this untimely end to their splendid efforts on behalf of British industries at the Exhibition.



Electrician Photo

VIEW OF A PORTION OF THE MAIN FRONT OF THE EXHIBITION, BEHIND WHICH WAS THE BRITISH SECTION.

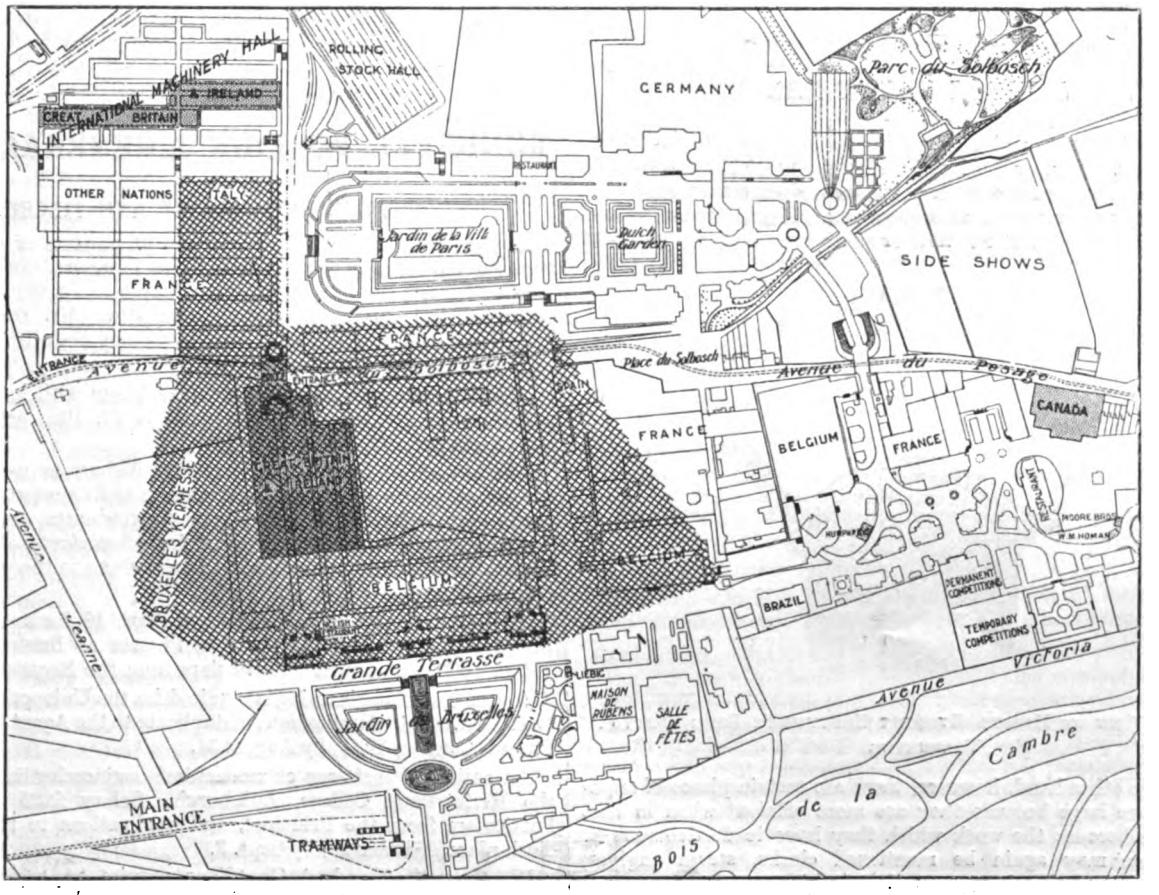
* According to the Oerlikon Co., the motors (single speed, 300 revs. per min.) would weigh about 40 tons and cost about £3,000 each.

Digitized by Google

The British section proper, which adjoined the Belgian building, has been entirely wiped out, and many important exhibits of electrical instruments and apparatus were consumed by the flames. The section contained no heavy machinery exhibits, as these were displayed in the International Machinery Hall, which is situated beyond the Italian section, and was not reached by the fire. Among the electrical and allied firms exhibiting in the British section were Kelvin & James White, the Morgan Crucible Co., the Reflector Synd., Cambridge Scientific Instrument Co., Gambrell Bros., Nalder Bros. & Thompson, John Dugdill & Co., Faraday & Son, R. W. Paul, British Aluminium Co., J. J. Griffin & Sons, Thermal Synd., Doulton & Co., and the Synchronome Co. The last named had equipped the whole of the British section with their well-known system of electric clocks, and the company suffers considerable loss in that its exhibit was not covered by insurance.

The daily press is loud in its complaints against the Exhibition authorities for the inadequacy of the water service and inefficiency of the fire brigade. Continental practice in fire fighting does not appear to come anywhere near British standards, judging by the reports received. On the occasion of the recent visit of our representative with the British Press delegates to the Exhibition the fire which occurred in the Café Monico about the middle of July was fresh in every one's mind, and the conduct of the fire staff was generally the subject of criticism. The interference of officials, who either refused to allow water to be turned on or insisted upon its being turned off, was the cause of the spread of the fire and nearly occasioned a general outbreak. The extent to which this official interference was carried may be gathered from an amusing incident. One of the British exhibitors in the International Machinery Hall, which is not far from where the Café Monico stood, is showing an internal combustion pumping plant. A feature of the exhibit is the actual raising of water to a given height from which it falls into a feed tank, being constantly circulated. No regular demand is made upon the water mains, but the water may be seen falling in a large stream from the delivery to the feed tank. When the Café Monico was burning the order was given to turn off the water from those exhibits which regularly required it, but an official noticed that this particular exhibit was still in operation and that water was issuing as usual from the delivery tank. Although he was assured that the same water was being used over and over again, he insisted upon the plant being shut down, as he felt sure that this course would materially assist the efforts of the brigade in putting out the fire.

It is always easy to be wise after the event, but disasters of this kind constitute that class of bitter experience from which it is usually possible to profit. An examination of the adjoining plan of the buildings of the Brussels Exhibition will show the circumscribed character of the British exhibit, and it is easy to see how difficult it would be to save this section should fire break out in the adjoining buildings. While considerations of ground space must, of course, be taken into account in the planning of a large international exhibition, at the same time the possibility of fire should exercise some influence on the general scheme adopted. For this reason it would appear to be a wise plan to isolate buildings as much as possible, so that anything in the nature of a general conflagration could be prevented by concentrating the efforts of the fire brigade upon the particular structure affected. The German section of the Exhibition is standing at the present moment mainly upon this account. It is entirely separated from the main buildings, as reference to the plan will show, and the wisdom of collecting the whole of the German exhibits in a distinct group of buildings has been fully justified by events.



PLAN OF BRUSSELS INTERNATIONAL EXHIBITION, SHOWING PORTIONS DESTROYED BY FIRE.

The disaster will cast a shadow over the Exhibition, and will probably militate against its success as a financial venture. Practically no damage has been done to the Machinery Hall, so that engineers who contemplated visiting the Exhibition may still do so without fear of disappointment. On the other hand, the Belgian, British, French and Italian sections proper each contained special exhibits of engineering and electrical interest, and these exhibits, unfortunately, have been involved in the flames.

STREET LIGHTING AT FINSBURY (LONDON).

It has been announced in the public journals that Finsbury (London) Borough Council havegranted a 10 years' contract to the Gas Light & Coke Co. for the lighting of all the streets in the borough by gas, and the statement has been further made that this decision has been come to after careful inspection and consideration of the latest examples of gas and electric lighting and their relative cost.

As usually occurs where gas and electric lighting interests are involved, statements are made which are not in accordance with the facts. One of the publications in which the statement we have referred to has appeared is the "Municipal Journal," and Mr. H. B.

Digitized by Google

Renwick, general manager and secretary of the County of London Electric Supply Co., has written to that journal the letter set out below. It is well that the public should have the exact facts before them in regard to the subject of public lighting :—

My attention has been called to a paragraph appearing in your issue of the 29th ultimo relative to the contract recently entered into by the Finsbury Borough Council with the Gas Light and Coke Company for the lighting of the borough. You state that "this decision was taken after the latest examples of gas and electric lighting had been carefully inspected and relative costs compared."

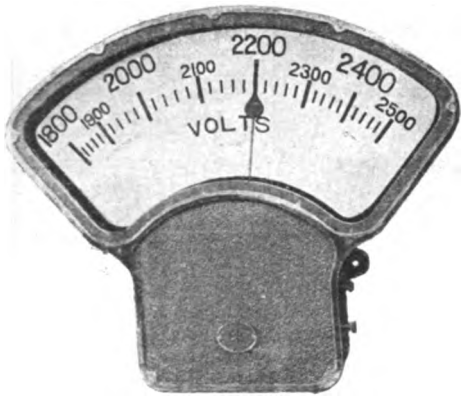
I am not in a position to say what were the latest examples of gas and electric lighting inspected by the Council, but I do know that my company offered to submit examples of electric lighting free of expense to the Council, but this offer was declined.

With regard to the question of relative running costs, my company submitted a tender for lighting which gave an illuminating power three times as great as the existing gas lighting, and, moreover, showed a saving in running costs as compared with gas of over 14 per cent. In spite of this, however, the company's offer was declined.

In view of the mistaken impression which the paragraph in question is likely to convey to your readers, I trust you will find space for this letter in your next issue.

A LARGE VOLTMETER.

A large instrument or piece of equipment may owe its size to one of two things. It may be large and even unwieldy because its manufacture has not reached a very high state of perfection, or because the making of its parts is not an easy matter. Clocks, steam engines, electric motors have all at one time or another been examples of this



General View of Messrs. Everett Edgcumbe's Large Sector Voltmeter.

law. On the other hand, however, there are certain pieces of apparatus that are large because they are more efficient when in that condition or because the work which they have to do demands it. Among these may again be mentioned clocks, steam engines, electric motors and also, it appears, electrical instruments.

For Messrs. Everett, Edgcumbe & Co. inform us that they have lately been supplying a few extra large patterns of sector voltmeters, especially designed for central station work. The accompanying illustration shows one of these instruments, which is, it is claimed, the largest that has ever been supplied either in this country or abroad.

The actual length of the scale is 2 ft. 1 in., and these instruments are intended to be employed in large central stations, so that the engine driver will be able to see from any position in the station the exact voltage of the system. In one particular central station, where there is both alternating and continuous current, two voltmeters have been supplied, one for use on the alternating-current side and the other for use on the continuous-current side.

As will be readily understood, the designing of an instrument having this extremely long scale was rather special when the size and weights of the moving parts are taken into account, but Messrs. Everett, Edgcumbe & Co. inform us that these instruments are quite as dead-beat as an ordinary 6 in. dial instrument, and every whit as efficient.

Railway Station Lighting.—The Lancashire & Yorkshire Railway Co. is making steady progress with the work of substituting electric for gas lighting at the stations on the Southport line. The last station to benefit from the change is Waterloo, where the increased illumination is a great improvement.

LEGAL INTELLIGENCE.

Workmen's Compensation.

At Hastings County Court on Monday, before Judge Scully, Wm. Remane claimed compensation from the Hastings & District Tramways Co. for loss of his employment as a motorman through defective eyesight, alleged to have been caused by the flashes and sparks that flew from under the cars, which are worked on the Dolter surface contact system on a portion of the route.

Applicant stated that he had been in the German Navy and the English mercantile marine, and had not suffered from any trouble with his eyes. On Feb. 1 last, while driving a car up a hill, he had an accident through a mist suddenly coming before his eyes. Afterwards he noticed that the mist came after he passed other cars that were flashing and sparking on the Hastings Front, where the surface contact system was operated. So, having seen a doctor, he informed the general manager of the company that his eyesight was defective and left the company's service. He denied that he had had previous trouble with his eyes, but admitted that once when he went to the East Sussex Hospital the doctor told him he was short-sighted. Both at Bristol (when employed on the tramways there) and at Hastings he had passed eye tests quite satisfactorily.

His Honour adjourned the hearing, remarking that he had heard of no similar case.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the vacant position of assistant lecturer in the physics department of the Technical College, Sunderland. Commencing salary £150 per annum. Particulars from the assistant clerk to the Education committee (Mr. Herbert Reed), 15, John-street, Sunderland. Applications by Sept. 10. See also an advertisement.

A shift engineer is wanted for power house with h.t. alternating and d.c. plant. Salary £2. 5s., rising to £2. 10s., per week. See advertisement.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Candidates must be graduates, and must have had experience in the test room of first-class electrical engineering firm. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

A professor of engineering is required for the University of Queensland (Australia). Applications in duplicate to the Agent-General, 409, Strand, London, W.C., by August 31.

An assistant professor of mechanical engineering is required for the Heriot-Watt College, Edinburgh. Salary £225 per annum. Particulars from the Principal, and applications to the Clerk, 20, York-place, Edinburgh, by Sept. 3.

Wandsworth (London) Guardians require an engineer and an assistant engineer. Salaries £2. 17s. 8d. and £2. 2s. per week respectively. Applications to the Clerk, St. John's Hill, S.W., by Oct. 31.

The Governors of Faraday House have appointed Mr. E. A. Nash, A.C.I.S., A.I.E.E., as secretary and business manager of the Electrical Standardising, Testing and Training Institution, in place of Mr. Howard Foulds, who has recently secured an appointment in Birmingham.

The following appointments have been made by the Council of the University of Manitoba :—

Mr. J. W. Dorsey to be lecturer in mechanical and electrical engineering; Mr. Geo. Halstead, M.Sc., lecturer in materials and hydraulics; Mr. J. R. Thomson, B.A., B.Sc., lecturer in drawing; Mr. Lloyd A. H. Warren, M.A., lecturer in mathematics; Mr. T. A. Neelin, B.A., demonstrator in physics; and Mr. B. Olson, B.A., demonstrator in chemistry.

The Walsall Electrical Co. have appointed Mr. C. F. Thompson, Glenbank, Woodland Park, Newport (Mon.), as their sole agent for Gloucester, Monmouthshire and South Wales.

EDUCATIONAL NOTICES.

University of London, University College.—We have received a copy of a pamphlet which gives particulars of the faculty of engineering and school of architecture. The faculty includes the departments of mechanical, electrical, civil and municipal engineering, and

Digitized by Google

provides students wishing to devote themselves to engineering with a systematic training by means of lectures, tutorial classes, drawing, laboratory and practical classes, in the application of scientific principles to industrial purposes.

The courses are also suited to the requirements of students who intend to enter for appointments in the Indian Public Works Department, engineering department of the G.P.O., department of the director of engineering and architectural works in the Admiralty, Patent Office and other similar services, or of those who intend to become patent agents, architects, technical teachers, chemical engineers, &c. The engineering departments have been recognised by the Board of Trade as providing suitable technical training for marine engineers, and a student who has satisfactorily attended a three years' course may be exempted from two of the four years' workshop training required.

The Pender Professor of Electrical Engineering is Prof. J. A. Fleming, M.A., D.Sc., F.R.S. (Dean of the Faculty), and he is assisted by a capable staff of assistants. The courses of instruction are arranged to cover: (1) Ordinary and special training for the profession of electrical engineering by lecture and laboratory courses; (2) undergraduate lecture and laboratory courses covering the range of study required in preparation for graduation (B.Sc. in engineering) in the University; and (3) special advanced research and post graduate work. A special feature is the electrical research laboratory, which is fully equipped for teaching and research in connection with radio-telegraphy and high-frequency currents. The lecture accommodation is good and the plant and apparatus at the laboratories are up to date.

In the mechanical and civil engineering departments the courses of instruction are so designed that engineering students receive a thoroughly sound practical and scientific training.

Facilities are also provided in each department for post-graduate and research work in all the subjects.

Intending students should communicate with the Provost or the Dean of the Faculty, not later than Sept. 20.

University of Manchester.—The new session commences on Oct. 4. New and enlarged engineering laboratories have been erected. Prospectuses, giving particulars of the lectures, laboratory and drawing courses in engineering and physics, &c., may be obtained from the Registrar.

University of Bristol.—At this university complete courses of instruction in electrical, mechanical and civil engineering are given, and also instruction in the evening classes. The 1910-11 session in the faculties of arts, science and medicine will commence on Oct. 3, and in the faculty of engineering on Sept. 13. Particulars and prospectuses from the registrar, Mr. James Rafter.

Merchant Venturers' Technical College.—The faculty of Engineering of the University of Bristol is provided and maintained at the Merchant Venturers' Technical College. There are complete courses of instruction in civil, mechanical, electrical, mining and motor car engineering. Calendar (6d.) or prospectus (1d.) may be obtained from the Registrar.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

University College, Dundee.—The new Peters electrical engineering laboratory will be opened on Oct. 6, when Prof. E. Rutherford will deliver an address.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Glasgow and West of Scotland Technical College.—The day classes begin on Tuesday, Sept. 27, and the evening classes on Thursday, Sept. 22. The diploma of the College is granted in civil, mechanical and electrical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study for the diploma usually extend over three sessions, and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow after attendance for at least one session upon prescribed University classes. Preliminary examinations begin on Sept. 19. There are new and well-equipped laboratories in the departments of physics, chemistry, mechanics, motive power and electrical engineering, &c., and facilities are afforded for research. Copies of calendar (price 1s. 4d.) and prospectus (gratis) can be obtained from the Secretary.

Technical School Regulations.—Revised regulations of the Board of Education for technical schools, &c., have been issued, together with a memorandum by the Permanent Secretary to the Board (Sir R. L. Morant).

The changes introduced are mainly for bringing out more clearly the intention of those regulations and guarding against irregularities which have been apt to grow up in practice. Largely owing to the activities of local education authorities and other bodies, various new types of school and class have come into existence since the passing of the Education Act of 1902 which were not directly contemplated when the regulations were framed. The Board hope, therefore, to issue before the end of the current year a body of new regulations, which will come into force on Aug. 1 next and will make more adequate provision for the co-ordination of continuation schools by local education authorities, for the grouping of subjects into organised courses and the improvement of the attendance of students. It will be necessary to provide simpler and more suitable means of allocating the grants payable under the regulations of the Board of Education to institutions of university rank, and for co-ordinating these grants with those paid to the same institutions by the Treasury. Separate regulations will accordingly be arranged for this purpose. The Board must be satisfied that the courses provided are adequate in range and length, and that the students are regular in their attendance, but it is hoped that these requirements can be secured without interfering with the freedom of universities to work out their curricula in the ways best suited to their individual needs. It is required that the attendances of students shall in future be recorded in registers supplied by the Board. This requirement, however, will not necessarily apply to technical institutions of university rank recognised under the regulations. The present regulations are limited to those determining the conditions of grant. The Board have under consideration certain changes as regards the science and art examinations, the national competition and the awards to students.

BRITISH NOTES.

Aberdeen.—On Monday the City Council decided to establish on all the tramway routes a series of ½d. fares for a maximum of 740 yds.

Carmarthen.—Public electric lighting was inaugurated on 1st inst. by the Carmarthen Electric Supply Co., which is supplying current to 238 public lamps from temporary plant by overhead cables.

The company has secured a 14 years' contract from the Council, who are making a saving of £200 a year by the change from gas to electric lighting. When the generating station has been completed there will be an official inauguration of the scheme by the mayor (Ald. Walter Lloyd). The generating plant consists of two 50 H.P. gas engines and two 35 kw. d.c. dynamos, with a battery of Tudor cells.

Carnarvon.—The National Eisteddfod Pavilion is being wired for the electric light at a cost of £40.

Caversham.—Reading & District Electric Supply Co. have notified the Council of their intention to extend their electric supply mains into this district.

Darlington.—An unopposed inquiry was held last week into the Council's application for sanction to borrow £1,500 for extensions of the plant at the electricity works.

Dunfermline.—The Council have been in communication with the Board of Trade in regard to the transfer of the Dunfermline provisional electric lighting order to the Fife Electric Power Co.

The Board refuse sanction to the arrangement for the transfer, as the clause in the agreement providing for the purchase of the undertaking by the Corporation between 30 and 40 years hence is deemed practically worthless. The agreement provided that the lighting customers of the company should be transferred to the Corporation on certain conditions, but that users of electric current for power (except where the current consumed did not exceed 4 H.P.) should be retained by the company, the object being that the company might retain their large consumers. The Council is asking the Fife Co. to submit terms more acceptable to the Board of Trade.

Electricity in Blasting.—At inquests on three men who lost their lives as the result of an explosion at a limestone quarry in Penmon, Anglesey, on 11th inst., the jury found that the explosion was an accident, and that it might have been caused by a smouldering fuse in the hole which the men were at the time charging with gunpowder. The manager (Mr. George Finsland) accepted a sug-

Digitized by Google

gestion from the inspector of mines, to use electricity instead of ordinary fuses, the inspector stating that electricity was much safer.

Electricity in Mining.—In his annual report H.M. Inspector of mines for the Southern District (Mr. J. S. Martin) states that the use of electricity has been increased at South Crofty Mine (Cornwall) and it has given general satisfaction throughout the year. At the various mines where electric plant has been in operation it has been continued, except (he believed) at Wheal Busy, where those responsible for its adaptation had not in any way benefited themselves nor anyone else by the manner in which things were carried out.

The principal installations are at Great Dowgas, Wheal Jane, Wheal Vor, St. Ives Consolidated, &c. East Pool and South Crofty, &c., have been taking their supply of electric energy with mutual satisfaction from the local power company, the former for conveying the mineral to its Tolvadden dressing floors. Dolcoath Mine (Ltd.) has during the year concluded a contract with the Cornwall Electric Power Co. and the Urban Electric Supply Co. for the supply of power to the mine generally, and considerable saving in fuel consumption and wages is anticipated. It has been decided to adopt plunger pumps (electrically-driven) in Williams' shaft. This pumping installation will be very compact, everything will be in duplicate, and the several parts will be interchangeable.

Grassington (Yorks).—At a meeting of the Grassington Electric Supply Co. last week it was reported that the demand for electric current was increasing and negotiations were proceeding for adopting electricity for street lighting.

Hospital Lighting.—Hyde Council have agreed to wire the borough infectious hospital.

Huddersfield.—The salary of the tramways manager (Mr. R. H. Wilkinson) has been increased from £375 to £400 per annum.

Launceston.—The Council are in negotiation with Mr. J. A. Purves as to the supply of electricity. At present a provisional order for the district is held by the Electric Supply Corpn., but there is no provision for a transfer.

Leeds-Morley Tramways.—A scheme has been arranged between Leeds Tramways committee and Morley Corporation for the extension of the Leeds municipal tramways to Morley, about 7 miles distant. Morley Council possess parliamentary powers to construct the lines and Leeds will construct and lease them.

Light Railway.—The Light Railway Commissioners have submitted for confirmation to the Board of Trade an order reviving the powers granted by the Wolverhampton and Cannock Chase Railway (Light Railway) Order, 1907. Objections to the Board by Aug. 31.

The Board of Trade have recently confirmed the order of the Light Railway Commissioners for the construction of a light (electric) railway from Bacup to Shawforth. The line, which will be constructed at once, will make connection with the Rochdale tramways.

London and Croydon Through Tramway Booking.—We have received particulars of the results of the first year's working of the through bookings on the tramways between Croydon and London from the opening of the L.C.C. Streatham to Norbury tramway extension on July 31, 1909, to July 30, 1910 (inclusive).

On the Norbury and Purley route 1,058,696 car-miles were run and 10,448,687 passengers were carried. The total receipts amounted to £39,558. 13s. 7d., an increase of £13,831. 8s. 2½d., the average weekly increase being £265. 19s. 9d. The through bookings issued were: By London County Council, 508,504; by Croydon Corporation, 569,548; total, 1,078,052. Croydon issue over L.C.C., 61,044. The values were: By London County Council, £6,025. 0s. 4½d.; by Croydon Corporation, £7,111. 2s. 2d.; total, £13,136. 2s. 6¾d. The Croydon value over L.C.C. system was £1,086. 1s. 9½d. The proportions due are: To London County Council, £8,948. 7s. 1d.; to Croydon Corporation, £4,187. 15s. 5½d.

Notts and Derbyshire Tramways.—The light railways in the Ripley district, which form part of the scheme of the Nottinghamshire & Derbyshire Electric Tramways Co., are shortly to be constructed.

Patent Decisions.—It is announced that an order has been made by the Controller-General of Patents revoking the letters patent granted to Harry Wharton for an invention for "Improvements connected with pulley blocks, cranes and other hoisting gear," No. 20,342 of 1902.

An order has been made restoring the letters patent granted to John Schade, jun., for "Improvements in spring terminal clips for electric conductors," No. 17,879 of 1904.

Personal.—Mr. W. Perren Maycock, M.I.E.E. (who has recently completed an 18 months' engagement with the Int. Corres. Schools), is resuming his consulting and literary work. For some time Mr. Maycock has been engaged on a new edition of "Electric Wiring, Fittings, Switches and Lamps." This will be published by Messrs. Whittaker & Co.

Presentation.—On the occasion of his marriage Mr. T. H. Saul, of the Acton electricity staff, has been presented with a canteen of cutlery and a silver sugar bowl.

Rawtenstall.—The Council have obtained authority to construct an additional tramway from Waterfoot to Water. Six new single-deck cars are to be purchased.

Reigate.—A committee of the whole Council has reported that they have approved the adoption of Diesel oil engines at the generating station.

The chairman of the Electric Light committee (Ald. BARNES) explained that for the year ending March 31, 1909, the revenue was £5,812 and the expenditure £3,453, leaving a net profit of £2,358.

Dr. COLMAN hoped that smaller householders would be able to obtain electric current in the same way as they were at present supplied with gas.

School Lighting.—Abertillery Education committee have decided to wire the Aberbeeg and Brynhyfoyd schools.

Stockton-on-Tees.—The local Chamber of Commerce have invited Sir Clifton Robinson to meet them in order to discuss extensions of the local tramways.

Sunderland.—The chairman of the Electricity committee and the borough electrical engineer (Mr. A. Blackman) have been authorised to visit Marylebone (London) electricity supply department for the purpose of obtaining information as to the methods adopted for increasing the number of consumers of electricity.

Ald. BRUCE stated at the last meeting of the Council that, owing to the decrease in the units for lighting, which was not due to any loss of customers, but entirely to the fact that metal filament lamps would give an equal light with a decrease of units, the committee felt that the time had come when they should do something in the way of canvassing. Marylebone had a system of canvassing in operation which had resulted in turning a debit of £3,090 in 1909 to a credit balance of £8,482 in 1910. The promoters of an electrical exhibition which was to be held in Sunderland in September and October had asked the committee to make a small contribution to the exhibition and supply them with current free of charge. As the committee thought the local undertaking would reap the greatest advantage by it, and it would be a splendid advertisement, they proposed to support the exhibition as desired.

The report was adopted.

Tramway Fares.—On the London United Tramways a new scale of fares has been introduced. Each route is now divided up into sections, any consecutive three of which may be traversed for 1d., six for 2d., and so on; the charge for one additional section is ½d., i.e., four consecutive sections for 1½d., seven for 2½d., &c.

On the tramways in the Potteries district the ¼d. "fair fare" system is to be abolished on Sept. 1, and ½d. stages introduced.

Tramway Provisional Orders.—In the 1910 session of Parliament only three applications were lodged with the Board of Trade for provisional orders under the Tramways Act, 1870 (from Huddersfield and Rawtenstall Corporations and Milnrow Urban Council). Each of the applications was for power to construct additional tramways. The aggregate length of the proposed tramways was 2 miles 7 chains of double line and 4 miles 63 chains of single line, and the estimated cost was £67,376. Orders were made and confirmed in every case.

Tramway Workers' Conference.—At the annual delegate meeting of the Amalgamated Association of Tramway and Vehicle Workers at Manchester on Friday the following resolution was passed:—

That the time has arrived when the following alterations in the conditions of labour should be conceded by the tramway authorities throughout the country:—(1) An allowance of not less than 30 minutes per day for booking on and off duty; (2) That all spare men be guaranteed not less than 48 hours per week; (3) That all time from signing on duty to signing off duty be paid for except such time as may be mutually agreed upon as reasonable for the purpose of meals.

Underground Telegraph Wires.—The Postmaster-General has decided to lay underground telegraph wires between Leeds and Hull.

Ventilation of Buildings.—The Medical Officer of Health of Westminster, London, in his annual report states that it is not uncommon to see in restaurants and business places electric fans at work having no communication with the outer air. These fans do not act as ventilators, but merely agitate the air, probably already heated and vitiated. Experiments have been carried out by two French doctors (MM. Sartory and Filassier) proving that these fans cause draughts, stir up the dust and distribute it through the rooms, so that, after running for one or two hours the number of organisms and dust particles in the air is enormously increased. They therefore recommend that all shafts and tubes used for bringing or taking off air should be frequently cleansed.

Wigan.—The general manager of the Liverpool Corporation tramways department (Mr. C. W. Mallins), who was recently called in to report on the position of the Wigan tramways, has issued his report.

The gross capital expended on the tramways at March 31 last was £508,073, 8s., but from Ince Council, for purchase of lines within their area, there had been received £24,033. 14s., leaving the expenditure £484,039. 14s., less loans redeemed and sinking fund amounting to £90,705. 19s. 11d., or net £393,333. 14s. 1d. The total length of route was 23 miles 6 fur. 126 yds., and the cars in stock 67. From the amount

Digitized by Google

expended on capital account, the undertaking appeared to be considerably over-capitalised, accounting to some extent for the loss in working the concern. Nothing had been set aside for renewals, which would become very urgent in the not distant future. Mr. Mallins was convinced that the loss would have been much greater but for the economies which had been practised by the committee responsible for the undertaking. As regarded the permanent way, it was most unfortunate that two gauges should have been introduced on one system. The narrow gauge should be abolished as soon as the financial position warranted. £305,208 seemed to have been expended on the permanent way (£9,877 per mile), which seemed excessive against £6,132 per mile expended on 15 typical municipal tramways throughout the country. That gave an excessive capital expenditure of £115,730, and a corresponding excessive payment of annual interest and sinking fund of £6,292. The £57,421 and £1,858 per mile expended on overhead equipment appeared also excessive, compared with £1,524, the average cost on 15 other tramways. Under that head an excessive capital expenditure of £10,329 had been incurred, involving £561 for interest and sinking fund. On car sheds, buildings, &c., the capital expenditure of £1,234 per mile of track was above the average (£1,054). That gave as excess £5,864, which involved £319 for annual interest and sinking fund. On rolling stock Mr. Mallins states that the £792 per car is above the average of £672, the total excess being £8,047, or £437 for interest and sinking fund.

In regard to the question of over capitalisation, Mr. Mallins observes that one way of dealing with the matter would be to expend a further sum for doubling the lines wherever possible through the system. If, however, the committee did not feel justified in expending the large amount necessary for this, he believes that £51,000 approximately would be sufficient to correct the mistakes which had been originally made in planning the track and in the kind of rolling stock purchased. This amount would provide 50 additional passing places, the lowering of the surface under 11 bridges, the committee's proportion of construction of three junctions for through running with adjoining tramways, and additional junctions and lines in market-place, &c., as also 40 new double-deck cars. The improvements should be introduced gradually, and he was not without hope that if £23,416 were spent for these purposes the system could be made a paying concern. The second moiety of the improvements could be carried out later, subject to the success of the smaller scheme. The alternative would be to lease the lines to a company who would relieve the Corporation of all further liability.

Mr. Mallins considers that great care must have been exercised by those responsible for the control of the traffic department; indeed, had the other departments of the undertaking been managed as economically there would have been no loss on the concern. The traffic prospects in Wigan appeared to be fairly good on most of the routes. General expenditure in the engineering departments amounted to 0·892d. per car-mile, which compares favourably with other undertakings, but had electric current been supplied at the same price per unit as the average there would have been a considerable saving.

Mr. Mallins makes the following recommendations:—

1. The appointment of a general manager, responsible to the Tramways committee for the whole undertaking, with the possible exception of the permanent way. 2. That the maintenance charge on overhead equipment, rolling stock, car sheds and workshops should be reduced to the average. 3. That the cost of electric current be reduced to the average of tramway undertakings. 4. The cost of maintenance of permanent way reduced to the average. 5. An improved service. 6. A system of through running. 7. The contract for advertising on the cars be looked into, as to whether better terms could be arranged. 8. A rearrangement of the present stages and fares. 9. A more up-to-date type of rolling stock; and 10. The standard gauge be substituted for the narrow gauge portions of the routes.

Wireless Telegraph Notes.—The great usefulness of wireless telegraphy in connection with seafaring matters is now firmly established. An instance of its utility in combination with the submarine cable is now reported from Durban, Natal. The British warship "Hermes," whilst at sea off the coast of Natal, by means of a wireless message became acquainted with an accident which had happened to a ship, the "Combermere." After rendering assistance and supplying the "Combermere" with some spares, the "Hermes" communicated news of the accident to Durban by wireless, and a message was sent over the cables of the Eastern & South African Telegraph Co. to the owners of the "Combermere" in London, so that within a few hours of the accident becoming known on board the "Hermes," London was informed of an event which had occurred on the high seas to a vessel six days out from Port Elizabeth.

In regard to the grounding of the British armoured cruiser "Duke of Edinburgh" on the Atherfield Ledge, off the Isle of Wight, between Ventnor and Freshwater, four miles west of St. Catherine's Point, in a fog on Saturday last, it is announced that immediately the accident occurred the Commander-in-Chief at Portsmouth was communicated with by wireless for assistance, and immediately the cruiser "Furious" and a number of dockyard tugs were despatched to the assistance of the "Duke of Edinburgh," which, however, was successfully refloated with very little outside help. It is calculated that if the worst had happened to the ship the timely notification of the occurrence and the prompt response would have prevented any loss of life.

The Marconi Company have made an offer to the Portuguese Government to establish wireless telegraph stations in the Portuguese colonies. It is stated that the Portuguese Government are favourably disposed to the offer.

In connection with the establishment of radio-telegraph stations in the Pacific, the following information from the "Australian Mining Standard" is of interest:—

Taking for granted that the Commonwealth and the New Zealand Governments will construct the Sydney and Doubtless Bay stations at their own expense, the cost of the remainder is estimated at £42,000, of which the Imperial Government's proportion would be £23,334, the Commonwealth's £12,833, New Zealand's £2,333 and Fiji's £3,500. The annual cost of maintenance was estimated at £13,820, to which Great Britain would contribute £7,716, the Commonwealth £4,234, New Zealand £748 and Fiji £1,122. There is, however, good ground for thinking that the cost of construction will be well below the estimate, the contracts of the Commonwealth for its Sydney and Fremantle stations each having a range of 1,250 miles, having been let for £4,150 each to the Australasian Wireless (Ltd.). In addition to this general scheme the Commonwealth Government will establish medium-power stations at Port Moresby and Thursday Island, so that Australia and Papua may be connected; specifications are now being prepared for these, and tenders will be invited at an early date. A telegram from Port Darwin, received last week, stated that the Governor of Timor purposes to visit Melbourne for the purpose of conferring with the Commonwealth Government on the question of connecting that island by wireless with Port Darwin.

COLONIAL AND FOREIGN NOTES.

Argentina.—H.M. Consul (Mr. H. M. Mallet), reporting on the trade and commerce of the consular district of Rosario for 1909, states that a number of foreign travelling agents now constantly visit the district, while their efforts, with the careful study of requirements and methods of trade, assist them to obtain large and profitable orders.

Competition for trade is keen, and agents and travellers from abroad are constantly on the watch to meet requirements, and merchants, on account of the less trouble it gives them, frequently avail themselves of this opportunity to replenish their stock. Among the more important items likely to be required are electrical fittings, hardware, agricultural machinery and implements, iron girders, &c.

Another large grain elevator (electric) has been erected at the port for a British firm.

Formerly (continues the report) British capital alone monopolised the construction of public works, such as railways, ports, trams, telephones, electric lighting, &c. At present, however, foreign capital (chiefly French, German and Belgian) is competing for such works, and has been successful in securing several profitable concessions hitherto worked with British capital. The valuable concession (a monopoly) held by a British company for providing electric light, &c., to the city of Rosario is about to pass into foreign hands.

The official value of the electrical appliances imported into Rosario during 1909 was $76,567 (gold), compared with $166,916 (gold) in 1908, the figures for railway and tramway rolling stock, engines, &c., being $10,100,006 (gold) and $14,670,349 respectively.

Buenos Ayres Western Rallway has asked Congress to grant a concession for the construction of a tube (electric) railway between Once and the Port, to be used for freight only, passenger traffic being catered for by the Anglo-Argentine Tramways Co., who propose to construct another tube railway.

The "Review of the River Plate" recently published statistics showing the proportion of the trade of Great Britain, United States and Germany in the leading imports into the Argentine Republic in 1908, from which we abstract the following:—

Railway cars, $6,029,924 (gold): U.K. 69 per cent., U.S. 14 per cent.; galvanised iron, $5,395,047 (gold): U.K. 86 per cent.; railway material, $4,987,187 (gold): U.K. 70 per cent.; machinery, $3,726,786 (gold): U.K. 34 per cent., Germany 33 per cent., U.S. 11 per cent.; locomotives, $3,394,498 (gold): U.K. 81 per cent.; steel sleepers, $3,183,193 (gold): Germany 57 per cent.; bar and sheet iron, $3,133,634 (gold): Germany 35 per cent.; galvanised iron wire, $1,680,510 (gold): Germany 64 per cent., U.S. 14 per cent., U.K. 13 per cent.; electric cables and wire, $1,511,155 (gold): Germany 59 per cent., U.K. 25 per cent.; steel columns and joists, $1,392,554 (gold): Germany 54 per cent.; bolts and nuts, $1,332,159 (gold): U.K. 41 per cent.; boilers, $582,707 (gold): U.K. 71 per cent., U.S. 19 per cent.; dynamos and motors, $576,823 (gold): U.K. 48 per cent., Germany 30 per cent., U.S. 11 per cent.; electrical goods, $508,463 (gold): U.K. 45 per cent., Germany 34 per cent.

Australasia.—Mr. Buchanan Black has again submitted his scheme for leasing the Creswick (Victoria) Council's water reserves for utilisation in the generation of electric energy for lighting and power on a large scale.

Mr. Black is reported to be acting on behalf of a syndicate formed to provide funds for preliminary expenses, and he is confident that if the necessary powers be granted the capital for the whole scheme will be forthcoming. The main proposal is to increase very largely the storage capacity at Bragg's Flat, and to utilise the water power to generate electricity for supplying energy in bulk to large consumers for power and other purposes. Subsidiary plants at other points might increase the

Digitized by Google

supply. It will be necessary to bring a bill into the State Parliament, and the co-operation of the Council is sought.

A new 750 kw. low-pressure A.E.G. turbo-generator is being put down at the Golden Horse Shoe mine, Kalgoorlie.

Mr. J. H. D. Brearley (Messrs. Noyes Bros.) has reported on the proposal to construct an electric tramway to connect certain of the southern and eastern suburbs of Melbourne. The line will be about 2½ miles in length and double track throughout. The total cost of construction is put at £27,450, including £17,800 for permanent way and overhead construction, and £7,700 for rolling stock.

A conference of the municipalities interested in the proposal to purchase the local cable tramways, and to electrify and extend the system, has been held, but consideration of the matter has been adjourned.

Contracts have been let to fell the bush along the transmission line between Waihi and Wairongami (N.Z.). The work of excavating, &c., is making satisfactory progress at Horahora Falls, and it is anticipated that there will soon be available at Waihi 6,000 H.P. to 7,000 H.P. for operating the various mining plants now being driven by steam. With a cheaper power the mining management will be in a position to handle and treat a large tonnage of lower grade materials; the period of paying working of the mines will be extended by the employment of electric power in this way.

Hobart City Council has entered into an agreement with the Complex Ores Co. for the supply of electricity for public and private lighting in the city.

Brazil.—A contract was recently entered into between the State and Mr. Henry J. Conill for the construction of a railway from the Bay of Camamou to Salto Grande de Jequitinhonha, on the boundary between the States of Bahia and Minas Geraes. Steam or electric traction may be used, and the concessionaire has the right to construct any necessary telegraph or telephone lines.

Santa Catharina State Government has contracted for the electric lighting of the capital for £32,500. The generating plant is being supplied by a London firm, and it is anticipated that current will be available by the end of August.

The value of the whole of the electrical appliances imported into Santos during 1909 was £102,106, against £77,087 in 1908 and £97,138 in 1907. Reports deplore the falling off of British interest in these imports.

Chile.—In the "Diario Oficial" of June 8 a decree was published authorising Mr. Owen L. McDermott to construct an electric railway between Antofagasta and Mejillones. Work must be commenced within 12 months and the line completed in two years from May 28 last.

Several other public works, including a railway between Puerto Montt and Taena (897 miles), are projected. Five concessions for the construction of 480 miles of railway have been made recently.

China.—The value of the electrical material imported into Canton during 1909 was £9,210, against £6,799 in 1908; engine and boiler fittings £2,454, against £6,446; machinery £19,054, against £15,212.

Denmark.—In the report for 1909 on the trade and commerce of Denmark Mr. Consul Liddell states that the use of the telephone in Denmark has become general with extraordinary rapidity. Not to find a telephone in the towns or even the country districts is rather the exception than the rule. In 1881 the Telephone Co. of Copenhagen had only 22 subscribers, but at present the number is about 33,000. This rapid increase has not been confined to Copenhagen alone, but has spread to the provinces, and Denmark, comparatively speaking, now possesses the most extensive telephone service of all European countries, having 33·2 telephones per 1,000 inhabitants, whereas Sweden has 31·7 per 1,000, Norway 23·3, Switzerland 22·8 and Germany 14·1.

Exhibitions.—The commission appointed by the Spanish Government to consider the expediency of holding an exhibition in Madrid have decided in favour of a Universal Exhibition being held there in 1913. Tenders for carrying out the undertaking are invited (from both Spaniards and foreigners), and must be sent in to the organising committee before Sept. 15. The committee's decision will be given before Oct. 30. The work must be begun before Jan., 1911, and be completed by March, 1913.

A Fibre Congress and Exhibition will be held at Sourabaya, Java, in July, 1911.

Germany.—H.M. Consul at Stettin (Mr. R. Bernal) reports that Brown-Boveri steam turbine and dynamo of about 3,000 k.w. will be installed at a cellulose factory being erected at Cavelwisch, near Stettin.

Italy.—The "Gazetta Ufficiale" of Aug. 2 contains a decree giving particulars of 21 telephone lines which are to be erected by the Government. The Rome to Naples section will be 161 miles, the Genoa-Milan section 108 miles, Venice-Udine section 79 miles and the Catania-Messina section 63 miles. The other sections are shorter.

In order to cope with the increased traffic on the railway between Milan and Varese, and in order that some of the heavy trains now run by steam can be worked by electric traction, the Italian Minister of Public Works is making arrangements for the purchase of a number of additional electric locomotives.

Rio de Janeiro.—It is reported that the Rio de Janeiro Power & Light Co. have started to supply current to 2,000 arc lamps for street lighting under their new contract with the municipality.

Russia.—In the report for 1909 on the trade of Russia and of the consular district of Moscow Mr. Consul H. M. Grove states that there was an increased demand for foreign iron and steel goods, including dynamos, locomobiles, gas engines, hand tools, &c. The increase in the total exports for 1909 was wholly due to the increased output of rails, of which 141,000 tons were exported in 1909, against 82,000 tons in 1908.

A new grain harbour at Odessa is projected. It is probable that electric cranes and elevators will be erected and the quays will be lighted electrically. The estimated cost of the scheme is £1,636,000.

Spain.—In his report for 1909 on the trade and commerce of Barcelona Mr. Consul-General Roberts states that the local electric light, tramway and gas companies are in German and French hands. The electric supply company is a German concern, which supplies about 40,000 H.P. in the city and its environs. The company uses German coal, shipped from Rotterdam by the Westphalian Synd.

A concession has been granted for the construction of a new tramway up the mountain situated at the back of Barcelona to Rabassada, a favourite suburban resort about 6 miles distant.

The electric light and power business is in the hands of two companies—one known as the Barcelonesa and the other as the Catalana. The former is a German undertaking. Electric light, although in very general use, is expensive, the charges being 1 peseta per unit for domestic purposes and 30c. for power.

A British company has purchased from the Spanish holders a concession for the construction of dams across the river Ebro at certain points, and are about to build a dam at a point some 20 miles from Mora del Ebro, at a cost of about £200,000. The water thus impounded will give from 30,000 H.P. to 50,000 H.P., and enable the company to supply all the towns and villages for 150 miles around with electricity. The total cost of the scheme is estimated at over £1,000,000.

The British Chamber of Commerce for Spain, which was started in April, 1903, is doing useful work for British trade and commerce.

The electrical material imported into Barcelona during 1908 weighed 1,434 tons (of which only 3 tons were from the United Kingdom), against 444 tons in 1908 and 1,689 tons in 1909.

Copper is imported into Spain in the form of bars, wires and tubes, mostly from France and Germany. The quantities of wire for electrical purposes are of relative importance, but British prices are stated to be too high to admit of British goods being imported. The United Kingdom takes the lead in the export of machinery, chemicals, coals, the total exports showing an increase of £75,000 over 1908.

Sweden.—The report for 1909 of H.M. Consul at Gothenburg (Mr. J. A. Duff) states that, though the general trade of the country was depressed during the year, electrical engineering made some progress.

The supply of power by one of the largest companies (Sydsvenska Kraftaktiebolaget) began in the course of the year. The Trollhattan Works, which began its delivery of power in 1908 from its provisional establishment, extended its lines in 1909 to Gothenburg, Alingsas and Skofde, and began supplying the last-named town with power. The Hemsjo Co. also started its new power station at Torsebro during the year. In Norrland only one large power station (the Ungers Industriaktiebolags power station at Arbra) was opened. Stora Kopparbergs Bergslags power station at Bullerforsen is still in hand. The power station of the Uddeholm Co. at Forshult and the Vasterdalalfvens Kraftaktiebolags power station at Mockfjard have commenced work, and Hellefors Bruks Aktiebolag have commenced the work of harnessing four of its waterfalls in Svartalfven. The town of Umea has begun the construction of a power station at Klabbole on the Umea River. The large steam turbine station at Gellivare was ready to start work at the close of the year.

The Swedish Water Power Association, which was formed in 1909 for the promotion of a rational use of the water power, has on its programme several questions of great importance for the economy of water power, such as better water legislation, control of rivers and lakes, &c.

In the iron trade the most important event was the completion of the experiments in iron ore reduction in electric furnaces of different types at the Domnarfvet iron works in which the victory fell to the Aktiebolaget Elektrometall. Thanks to the decision of the Swedish Iron and Steel Institute to devote 250,000 kr. to set up experimental works on a large scale at Trollhattan, this important matter for the Swedish iron industry has been brought much nearer to the commercial stage.

In the report for 1909 of Mr. Vice-Consul Neess (Landskrona) it is stated that electric supply was inaugurated during the year. Power is transmitted by overhead cable from the River Lagan (about 62 miles away).

Uruguay.—Extensive improvements are to be carried out at the harbour of Montevideo, including the provision of cranes, electric light and motor power plant, dock railway lines, &c. The text of the Government bill authorising the work has been published, and the total cost of the scheme is put at £2,808,000.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Birkenhead.—For the year ended March 31 the total receipts of the tramways department were £56,817, including £55,759 from passenger receipts.

The total working expenses came to £33,757, and after allowing for bad debts, &c., the gross profit was £22,683. Interest amounted to £9,984, sinking fund charges to £9,317, and interest on amount applied to redemption of debt £1,742, and the balance (£2,357) was transferred to renewals fund. The capital expended was £366,419, an increase of £2,990 during the year, but the outstanding loans only amount to £282,442. 12,283,344 passengers were carried and 1,201,476 car-miles run, against 12,124,297 passengers and 1,278,015 car-miles in 1908. The receipts per car-mile were 11·32d., against 10·53d.

Halifax.—The accounts of the electricity department for the year ended March 31 show a total income of £36,329.

Receipts included £18,823. 10s. 5d. from supply of current for private lighting, power and heating, £15,195 from traction, and £1,718 from public lighting, less £1,044 for discounts. Total working expenses were £20,060, which included £11,337 for generation, £3,256 for distribution, and £2,664 for management expenses and general establishment charges. Gross profit was £16,269, and after paying interest on loans, &c. (£7,922), sinking fund charges (£6,349), income tax (£115), the net profit was £1,883. After crediting balance brought forward (£156) and bank interest, and voting £1,000 in relief of rates, the balance (£1,158) was carried forward. The total capital expended on the supply department is £107,133, an increase of £2,671 during the year. There are 1,855 consumers (with the equivalent of 174,994 8 c.p. lamps) connected, against 1,797 consumers and 163,578 8 c.p. lamps in 1909. 5,477,369 units of electrical energy were sold, including 1,865,715 units for private lighting and power, 3,545,007 for traction and 66,647 for street lighting. There are 63 public arc lamps, and the public maximum supply demand was 2,870 kw. against 2,850 kw. in 1909.

The total receipts of the tramways department were £89,270, against £86,158 in 1908-9. Passenger traffic was £86,285 against £82,219, the luggage and parcel receipts were £1,625, and advertising on cars £972, against £2,314. Working expenses were £53,898 against £60,145, and gross profit £35,372, against £26,013. After deducting special expenditure (£762, against £17,982), interest (£11,861, against £12,201), sinking fund (£9,562, against £9,200) and preliminary charges (£122, against £172) there was a net profit of £22,307, against a deficit of £13,542. Total working expenses came to 6·947d. per car-mile (against 7·95d.) which included power expenses 1·869d. (against 2·095d.) per car-mile. The charge for current during the past year was 1d. per unit against 1¼d. in 1908-9. The car-mileage run was 1,862,068 against 1,815,692, and the units of electrical energy consumed for traction were 3,479,464 against 3,580,224. 16,323,755 people were carried, against 16,413,434 in 1908-9.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms, &c., may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 5 for the supply of 5,000 porcelain insulators to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 4 for the supply of telephone material to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

LONDON County Council invite tenders for the covering with asbestos tape of certain electric cables in manholes in the south of London. Specification, drawing, form of tender, &c., from the Clerk of the Council, Spring Gardens, S.W. Tenders by 11 a.m. Aug. 30.

LONDON County Council also invite tenders for wiring and fitting for electric lighting of the second section of the central car repair depot, Woolwich-road. Specifications, &c., from the Clerk of the Council. Tenders by 11 a.m. Tuesday, Aug. 30.

BOURNEMOUTH Tramways committee want tenders by Aug. 31 for reconstruction of 2½ miles of tramway permanent way and supply of 450 tons of rails, with fastenings. Specifications, &c., from the General Manager.

Tenders are wanted by 5 p.m. Aug. 25 for supply of telephone apparatus and cable (main central battery system and metallic circuit telephone switchboards, &c.) for the Lancashire County Asylum, RAINHILL. Specification, &c., from the Clerk.

CHELMSFORD Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

SOUTH DUBLIN Guardians want tenders by noon Aug. 24 for wiring and fitting the workhouse for electric lighting. Specifications, &c., from the Clerk on payment of £1. 1s.

ROCHDALE Electricity committee want tenders by noon, Aug. 31 for 12 months' supply of paper insulated cables. Specification from the engineer and manager.

POPLAR (London) Guardians want tenders by 6:30 p.m. Aug. 31 for 12 months' electrical supplies, ironmongery, packing and jointing, &c. Forms, &c., from the Clerk.

WEST HAM Guardians want tenders for 12 months' supply of electrical fittings, engineers' oil, &c. Tenders to the Chairman of the Board, at 11 a.m., Sept. 1.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS invite tenders for 12 months' supply of electrical accessories. Tenders by 11 a.m., August 24, to the Secretary, Storey's Gate, London, S.W.

The directors of the Powell Duffryn Steam Coal Co. (ABERDARE) invite tenders for stores, including electrical goods. Tenders to London office (101, Leadenhall-street, E.C.) by Sept. 12.

HACKNEY (London) Council want tenders by 7 p.m. Sept. 15 for extension of main switchboard. Specification from Town Clerk.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. Aug. 30 for supply of electrical sundries, insulators, wire and sulphate of magnesia. Local representation necessary. Further particulars from 72, Victoria-street, London, S.W.

Digitized by Google

Tenders will be received (up to 3 p.m. Sept. 13) by the Deputy Postmaster-General, MELBOURNE, for supply of 8,510 telephones. Local representation necessary.

Tenders will be received up to noon Sept. 1, at the offices of the chairman of the Board of Control, WINNIPEG (Manitoba, Canada), for supply and installation of 46,000 ft. of 13,000-volt three-core cable. Deposit of $1,000 (about £205) required. Specifications and forms from the Power Engineer, Winnipeg. Copy of specification and conditions may be seen by British makers at 73, Basinghall-street, London, E.C.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

MOSTAR (Austria-Hungary) municipality will receive tenders until Oct. 1 for the installation of electric generating plant.

TENDERS RECEIVED AND ACCEPTED.

The tender of G. Weymouth Proprietary (Ltd.) has been accepted for the supply and erection of the electric power plant, &c., required for the cordite factory at Maribyrnong, Victoria.

There were seven tenders, and it was stipulated that the plant must be of Australian manufacture, importers being, therefore, precluded from the competition. It was further stipulated that the plant must be placed in position within 20 weeks from the date of acceptance of tender. The lowest tender (at £7,459) was accepted. The plant consists of duplicate air compressors, hydraulic machinery, refrigerating plant, cold water and pneumatic circulating systems, feed pumps, electric motors and electric distributors.

Belfast Harbour Commissioners have accepted the tender of the British Insulated & Helsby Cables for the supply and delivery of 3¼ miles of 7/18 h.t. cables, paper insulated, lead covered, bound with a layer of jute, compounded, suitable for a 3,000 volt continuous current), and ½ mile of 7/18 rubber insulated cable to sample.

Sunderland Corporation have accepted the following tenders:—

W. Rickard (Ltd.), supplying cable for stock; W. G. Farrow & Co., w.i. piping and bends; and British Westinghouse Co., for a three-phase transformer.

Bury (Lancs.) Council have accepted the tender of Siemens Bros. & Co. for e.h.t. trunk mains.

Clacton-on-Sea Council have accepted the tender of I. Frankenburg & Sons for 440 yds. of cable at £29.

Wigan Council have placed an order with D. A. Ablett for extending the electricity station buildings.

Messrs. Dorman, Long & Co. have placed an order with the A.E.G. (Berlin) for a complete electric power plant, consisting of three mixed pressure turbo-alternators and one live-steam turbine (each of 1,280 kw.), which will generate three-phase current at 3,000 volts 40 cycles. There will also be three 600 kw. direct coupled generators, two 600 kw. transformers, an induction motor coupled to a 150 kw. d.c. generator, switchboard, &c.

BUSINESS NOTICES.

Messrs. Arthur Joppling & Co. have opened a branch office and stores at 16, Park-lane, Leeds, to deal with their business in the north of England, and Mr. A. Pyman has been appointed manager for the Leeds district.

The Melbourne (Australia) offices of the India Rubber, Gutta Percha & Telegraph Works Co. have been removed to 21 and 23, Elizabeth-street.

Messrs. W. G. Watson & Co. (Ltd.) has been formed to acquire the New South Wales business of J. A. Newton & Co. Proprietary (Ltd.).

The Welsbach Light Co. of Australasia has been appointed sole agents in Australasia for the Electric Construction Co. of Wolverhampton and London.

Messrs. Henry Wm. Davis and Harry Walter Hosier, electrical and surgical instrument makers, 43, Grafton-street, London, W.C. (trading under the style of H. & W. Davis), have dissolved partnership as from July 16. Debts by H. W. Davis, who continues.

Messrs. Kurt, Wm. Bacher, Hugh C. Taylor and Jas. R. F. Smith, electrical and mechanical engineers, of Hounslow, Middlesex, have dissolved partnership.

Siemens "Onewattlite."—A new development introduced some months ago by Messrs. Siemens Bros. Dynamo Works, Tyssen-street, Dalston, London, N.E., when placing their 100 c.p. lamps on the market, is now generally known to the trade as the "Onewattlite." Particulars of this have been widely circulated by the firm, and it is worthy of consideration by the contractor who is more particularly interested in supplying shop keepers and trade establishments. It consists of a 100 c.p. "Onewatt" lamp used in conjunction with a suitable design of "genuine" Holophane glass reflector fitted to a gallery which brings the lamp into true focus and obtains the best possible illumination effects. Holophane glassware is now widely known for its special reflecting capacity, and used in conjunction with the "Onewatt" drawn tungsten lamps, provides a cheap and efficient method of illuminating the display windows and interiors of shops. Contractors are specially asked to note that when ordering "Onewattlite" the price quoted is inclusive of glassware, gallery and 100 c.p. "Onewatt" lamp complete, with the exception of the lamp holder, and is readily fitted to any existing lamp holder which may be installed. In the case of new installations, however, it would be necessary to order lamp holders extra. The firm will be pleased to supply full particulars of this speciality to all contractors who are interested in the class of work mentioned.

"Metalik" Lamps.—With the lighting season now fast approaching, attention may be called to the advantages claimed by Messrs. G. M. Boddy & Co. for their "Metalik" lamps. Among these may be mentioned the fact that these lamps do not blacken with use. Messrs. Boddy also claim that their lamp infringes no existing patent, and that they indemnify all users from legal attack.

CATALOGUES, &c.

B.T.H. MOTORS.—We have received from the British Thomson-Houston Co. two lists, the first of which deals with motors designed for driving sewing machines, and the second with continuous-current motors and generators of the DG type. These are made in several styles, one of which has a flange fitted to the motor so that the latter can be connected with an air duct and thus be kept supplied with fresh air.

SIEMENS METERS.—Messrs. Siemens Bros. Dynamo Works send us a pamphlet giving details of their watt-hour meters. This meter, it is claimed, marks a distinct step forward in the construction of this class of instrument, as all the working parts can be replaced without tools, and the replacement of all or any parts does not necessitate recalibration.

ST. HELENS CABLES.—From the St. Helens Cable & Rubber Co. we have to acknowledge a catalogue, on the front of which are some illustrations showing the use of this firm's cables in pre-historic times. We confess we did not know the use of the electric drive had advanced so far in the days of the Ancient Britons. Various electrical accessories made by the firm are illustrated in the interior of the catalogue, the advantage of which is brought before the senses of the reader by means of rhyme quatrains.

CONTA LAMPS.—The Regina Arc Lamp Works, of Cologne, have sent us two catalogues dealing with their well-known "Conta" lamp, the advantages of which were recently set out in the pages of THE ELECTRICIAN. Full details of the operation and prices of these lamps are given.

BANKRUPTCIES, LIQUIDATIONS, &c.

The discharge in bankruptcy of Albert Clapham, trading in partnership with James W. Hunter at 101, Kirkstall-road, Leeds, under the style of the Yorkshire Motor Car & Electrical Engineering Co., has been suspended for two years.

The National Lighting Corpn. (Ltd.,) 35, Cock-lane E.C., is being wound up, and the first meeting of creditors and contributories will be held on Aug. 23, at 33, Carey-street, London, W.C.

A meeting will be held at 61½, Fore-street, London, E.C., on Sept. 13, to receive an account of the winding up of the Crystalate Mfg. Co. (Ltd.)

The Russian Engineering Co., Ltd., is being wound up voluntarily. Mr. G. Hagger, 16, Gt. George-street, London, S.W., is liquidator. Meeting of creditors on 29th inst.

17,761 DEUTSCHE ELECTRO-SPARLICHT GES. Closed circuit transformers. (Date applied for, 31/7/08.)

COMPANIES' MEETINGS AND REPORTS.

CLAUD HAMILTON (LTD.)—The accounts for the past year show an available balance (including £932 brought forward, of £6,207. After placing £400 to preference shareholders' reserve, the directors recommend a dividend of 7½ per cent., carrying forward £1,797.

COMPANIA ALEMANA TRANSATLANTICA ELECTRICIDAD—The directors report further increase in the business of the company during 1909, and although the capital has been increased from 72,000,000 marks (£3,600,000) to 80,000,000 marks (£4,000,000), and the debenture issue from 15,000,000 marks (£750,000) to 17,000,000 marks (£850,000), the dividend has been increased from 9½ per cent. to 10 per cent. At the recent meeting the chairman announced that they had secured the contract to supply electrical energy to the Anglo-Argentine Tramway Co., and it was expected that the tramways in Monte Video would shortly show better results. The directors did not propose to increase the capital at present, but if found necessary it would take the form of debentures. In Buenos Aires the output of current for the year amounted to 128,514,152 units, compared with 110,895,317 units in 1908. Out of that total the energy consumed was 100,826,968 units in 1909, against 86,355,995 units in 1908, an increase of 16·8 per cent. The profit amounted to 14,756,652 marks (about £737,830), compared with 12,430,763 marks (£621,538). The new connections in 1909 were as follows: 96,154 incandescent lamps (equal to 5,110 kw.), 1,011 arc lamps (924 kw.), 1,028 motors (4,037 kw.), 566 ventilators, &c. (363 kw.), and 631 kw. increased output to other stations. These increases represent 11,065 kw., equivalent to an increase of 16·05 per cent. over 1908. At the end of 1909 the connections comprised a total of 732,484 incandescent lamps, 6,972 private arcs (equal to 44,990 kw.), 1,427 street arcs and 543 in the port (equal to 1,146 kw.), 6,783 motors, 9,569 ventilators, &c. (equal to 33,248 kw.). Sales to other stations were equivalent to 1,524 kw.: tramways about 15,190 kw. The company had 26,074 clients and 28,666 meters, against 21,489 clients and 24,402 meters in 1908. The total length of mains was 2,492 km. (about 1,545 miles), and the total capacity of the power houses was 46,710 kw. The construction of the station at Dock Sud was well in hand at the end of the year, and at present 30,000 kw. was available.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—At the meeting last week Sir Geo. Gibb said that the meetings of the three tube railways were consolidated into one for the purpose of his remarks. He expressed regret that the proposal for the extension of the Charing Cross line from its present terminus (under the S.E. Railway) to the Embankment did not pass the committee of the House of Lords. Each of the three railways had shown an increase in traffics, and the total value of the additional traffic for the half-year was £10,940. The working of all the railways had shown a satisfactory decrease in expenditure. The traffic was a growing one, and the facilities were being more and more appreciated by the general public. The Charing Cross, Euston & Hampstead Co. had maintained its dividend at the rate of ¾ per cent. on the ordinary stock. The Piccadilly Co. paid a dividend at the rate of 1½ per cent., an increase of ½ per cent., and the Baker Street & Waterloo Co. paid a dividend at the rate of 2 per cent., an increase of ½ per cent.

MERSEY RAILWAY CO.—The train-mileage run during the half-year ended June 30 was 330,307, compared with 384,962 during corresponding six months of 1909, and the number of passengers conveyed was 5,948,152 (against 5,818,759), exclusive of season ticket holders. Total receipts were £54,652. 18s. 2d., compared with £53,227. 18s. 10d. Working expenses (exclusive of charges for pumping, ventilation and lifts) were £29,916. 4s. (equal to 54·74 per cent.), against £30,810. 9s. 10d. (57·88 per cent.). The charges for pumping, ventilation and hydraulic lifts amounted to £3,279. 11s. 9d. (6·0 per cent.), compared with £3,659. 11s. 11d. (6·88 per cent.).

MEXICAN LIGHT & POWER CO. (LTD.)—At the recent meeting (at Toronto) it was announced that the storage capacity had been increased, and 20,000,000 cubic metres of water were now on hand. The business prospects for the present year were excellent. The net revenue for the past year was $2,426,811. After paying fixed charges, and dividends of 7 per cent. on the preference shares and 4 per cent. on the common stock, $149,385 was carried forward.

MEXICO TRAMWAYS CO. (LTD.)—At the recent meeting it was stated that there was every prospect of improvement in the receipts of the company. The Xocohimilco line was now in full operation and the receipts were satisfactory. The net revenue for 1909 (in gold), after paying all expenses and fixed charges, amounted to $922,457·95, to

Digitized by Google

which must be added $371,350·17 brought forward. Four quarterly dividends at the rate of 6 per cent. per annum had been paid, $300,000 carried to reserve, leaving $416,344·12 to be carried forward.

TURNER, ATHERTON & CO. (LTD.)—The directors' report recommending a dividend of 12½ per cent. for the half-year (making 10 per cent. for the year) on the ordinary shares, was approved at last week's meeting.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—The directors' report states that the result of the past half-year shows a substantial improvement. The net revenue from investments and properties (deducting general expenses) amounted to £96,767. 14s. 1d. The net income from the operation of the power house was £45,416. 19s., but the interest on £1,000,000 4 per cent. first power house debentures, and a proportion of commission, discount and expenses incurred in connection with the issue, required £20,870, leaving a surplus from the power house of £24,546. 19s., making a total revenue of £121,314. 13s. 1d. After meeting the service of the £1,000,000 5 per cent. prior lien bonds, and of the £2,818,700 4½ per cent. bonds of 1,933, and the payment under the guarantee on Metropolitan District Railway assented extension preference stock the surplus was £26,392. 13s. 1d. Interest at the rate of 1 per cent. on £4,928,050 6 per cent. income bonds of 1,948 required £24,640. 5s., income tax thereon £1,437. 6s. 11d., leaving £315. 1s. 2d. for reduction of accumulated revenue deficiencies. Since the closing of the accounts £54,652. 5s. was received from the estate of the late C. T. Yerkes on account of unpaid calls on shares and interest. The traffic of the railway companies in which the company is interested is increasing satisfactorily, and a notable feature is the decrease, in each case, in the working expenses, notwithstanding increase in receipts.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, AND RECEIVERSHIPS.

NEW COMPANIES.

BRYANT & SONS (LTD.) (111,261)—Reg. Aug. 11. capital £3,000 in £1 shares, to take over the business carried on by E. T. Bryant at Bristol, and to carry on the same, and the business of mechanical and electrical engineers, &c. Private company. First directors, E. T. Bryant, J. J. Ballard, O. E. Bryant and S. W. Bryant. Reg. office, 42, Queen Anne-road, Bristol.

LUMINATOR WATER CO. (FOREIGN PATENTS) (LTD) (111,214)—Reg. Aug. 8, capital £5,000 in £1 shares, to take over a business of engineers, electricians, machinists, manufacturers of and dealers in electrical and other machinery, &c. Private company.

ORIZABA TRAMWAYS SYND. (LTD.) (111,297)—Reg. Aug. 12, capital £3,150 in 3,000 ordinary shares of £1 each and 3,000 deferred shares of 1s. each, to carry on the business of tramway, railway and omnibus proprietors, manufacturers of and dealers in tramways, accumulators, locomotives, dynamos, &c., and to acquire any tramways in Orizaba, Mexico. Private company. Provisional directors, M. E. Williams and J. E. Stevens.

SALERNO SYND. (LTD.) (111,301).—Reg. Aug. 12, capital £8,300 in 8,000 shares of £1 each and 6,000 shares of 1s. each, to obtain concessions, licences, or powers for the construction, maintenance and working of railways, tramways and other public works in the province of Salerno, Italy, or elsewhere. Private company. First directors, B. W. Bennett and L. Dini. Reg. office, Cross Keys House, Moorgate-street, London, E.C.

SIRENO CO. (LTD.) (111,315)—Reg. Aug. 13. capital £3,000 in £1 shares, to carry on business as manufacturers of and dealers in electric warning signals, motor horns, projectors, switches, taximeters and all kinds of accessories used in connection with motor cars, boats and aeroplanes. Private company. S. F. Tyler is permanent governing director. Reg. office, 46, Brewer-street, London, W.

STATUTORY RETURNS.

ALERT ELECTRICAL CO. (LTD.)—Return (dated Jan. 27) filed July 2, gives capital £2,000 in £1 shares. 708 shares taken up. £708 paid. Mortgages and charges, nil.

BRECKNELL, MUNRO & ROGERS (LTD.)—In return dated May 24 capital is £30,000 in 2,000 preference shares of £5 each and 20,000 ordinary shares of £1 each. 14,829 ordinary and 958 preference shares taken up. £1 per share called up on 767 ordinary and £5 per share on 958 preference. £5,557 paid. £14,062 considered as paid on 14,062 ordinary shares. Mortgages and charges, £7,600.

CAMBORNE ELECTRICITY SUPPLY CO. (LTD.)—The capital in return to May 18 is £10,000 in £1 shares. 607 shares taken up. £1 per share called up. £605 paid, leaving £2 in arrears. Mortgages and charges, nil.

CANADIAN ELECTRIC TRACTION CO. (LTD.)—Return to Dec. 31, 1908, (filed June 21, 1910), gives capital as £120,000 in £1 shares. 68,007 shares taken up. £53,000 paid on 53,007, leaving £7 in arrears. £15,000 considered as paid on 15,000 shares. Mortgages and charges, nil.

GORSEINON ELECTRIC LIGHT CO. (LTD.)—According to return to June 6 capital is £4,000 in £1 shares. 2,000 shares taken up and £1,998 paid. Mortgages and charges, £800.

INTERNATIONAL DOWSING ELECTRIC HEATING & APPLIANCES CO (LTD.)—The capital in return to Dec. 31 is £20,000 in £1 shares. 18,107 shares taken up. £7 paid. £18,100 considered as paid. Mortgages and charges, nil.

LEATHERHEAD & DISTRICT ELECTRICITY CO. (LTD.)—In return dated June 2 shows capital £35,000 in £1 shares. 34,200 shares taken up. £34,200 paid. Mortgages and charges, nil.

LISBON ELECTRIC TRAMWAYS (LTD.)—Return dated May 11 shows capital £1,250,000 in £1 shares. 634,026 ordinary and 425,553 preference shares taken up. £134,026 paid on 134,026 ordinary. £925,553 considered as paid on 425,553 preference and 500,000 ordinary. Mortgages and charges, £499,400.

LLANDUDNO & COLWYN BAY ELECTRIC RAILWAY (LTD.)—Return to March 14 gives capital as £100,000 in £1 shares. 99,400 shares taken up. £77,900 paid. £21,500 considered as paid. Mortgages and charges, £75,000.

LLANGOLLEN & DISTRICT ELECTRIC LIGHT & POWER CO. (LTD.)—Return to July 16 gives capital as £6,000 in £1 shares (2,500 preference). 1,754 ordinary and 360 preference shares taken up. £1 per share called up. £2,110. 15s. paid, leaving £3. 5s. in arrears. Mortgages and charges, £2,000.

W. LUCY & CO. (LTD.)—In return to July 4 capital is £15,000 in £10 shares (250 preference and 1,250 ordinary). 250 preference and 1,030 ordinary shares taken up. £10 per share called up and paid on 250 preference and 781 ordinary. £2,490 considered as paid on 249 ordinary. Mortgages and charges, £7,000.

PETERBOROUGH ELECTRIC TRACTION CO. (LTD.)—Capital in return to May 16 (filed July 19) is £60,000 in 6,000 ordinary and 6,000 preference shares of £5 each. 4,000 ordinary and 4,400 preference shares taken up. £42,000 paid. Mortgages and charges, £21,000.

MORTGAGES AND CHARGES.

THOMAS L. SCOTT & CO. (LTD)—Particulars of £3,500 debentures, created Aug. 20, 1909, have been filed, amount of present issue being £500. Property charged, company's undertaking and property, present and future, including uncalled capital. No trustees.

RECEIVERSHIPS.

ACCESSORIES MFG. CO. (LTD.)—Mr. H. A. McCann, King's House, King's-street, London, E.C., was appointed receiver on July 29.

MAGNETO CO. (LTD.)—C. H. MacPherson, 35, Newhall-street, Birmingham, ceased to act as receiver or manager on July 20.

CITY NOTES.

MEMORANDA (Aug. 18).—**Bank rate 3 per cent. (since June 9, 1910). Price of silver,** 24½d. per oz. Consols 80¾—81 for money; 80¾—81 for account. **Consols Pay Day, Sept. 1; Stock and Shares Continuation Days, Aug. 29 and Sept. 13; Ticket Days, Aug. 30 and Sept. 14; Pay Days, Aug. 12 and 31; Mining Shares Carry Over Day, Aug. 26.**

PRICES OF METALS (London).—*Copper*, cash, 55⅝; three months, 57¼. *Lead*, English, 12⅞—13; foreign, 12½—12⅝. *Spelter*, 23. *Tin*, English, 151½—153½; foreign cash, 154½; three months, 153¾. *Iron*, Cleveland, cash, 50/0, three months, 50/9.

BERLINER STRASSENBAHN GESELLSCHAFT.—The general manager of the A.E.G. (Herr E. Rathenau) has been appointed a member of the board, with a view (it is stated) of putting an end to the quarrel between the municipality and the company. The Berliner Electricitäts Werke, which supply power to the Strassenbahn is to be acquired by the Council.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the five weeks ended July 1 were 995,992, compared with 865,897 in the corresponding five weeks of 1909.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The warrants in payment of the dividends on account of 1910 on the preference and ordinary shares have been posted.

W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.)—The directors have declared interim dividends on the preference shares and at the rate of 10 per cent. per annum, tax free, on the ordinary shares for the half-year ended June 30, both payable Sept. 1.

LIVERPOOL DISTRICT LIGHTING CO. (LTD.)—An interim dividend for the past half-year at the rate of 4 per cent. per annum has been declared.

MATHER & PLATT (LTD.)—An interim dividend on the ordinary shares at the rate of 5 per cent. (tax free) for the half-year ended June 30 (at the rate of 10 per cent. per annum) has been declared.

METALITE (LTD.)—Letters of allotment and regret have now been posted.

NORTHAMPTON ELECTRIC LIGHT & POWER CO. (LTD.)—The directors are paying an interim ordinary dividend at the rate of 5 per cent. for the half-year to June 30.

SOUTH AMERICAN LIGHT & POWER CO. (LTD.)—The directors have declared a dividend of 5 per cent. for the past year, have placed £1,500 reserve and carried forward £628.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have been requested to appoint a special settling day, and to grant a quotation to £1,240,563 4 per cent. preference stock and £3,791,106 4 per cent. debenture stock of the *London Electric Railway Co.* (in lieu of the securities of the Baker Street and Waterloo, Charing Cross, Euston and Hampstead, and Great Northern, Piccadilly and Brompton Railways), and the further issue of £184,375 *Metropolitan District Railway* guaranteed stock (4 per cent.)

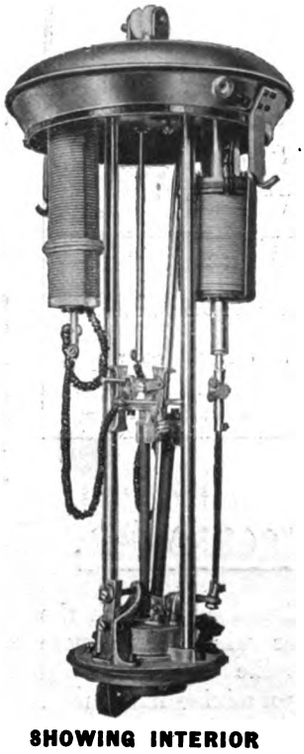
THE 'BUTT' FLAME ARC LAMP

(CONTA PATENT).



SHOWING INTERIOR ARRANGEMENT.

THE SIMPLEST yet MOST ROBUST ARC LAMP EVER PRODUCED !!

SELF-REGULATING.

Advantages :

NO COMPLICATED MECHANISM.

NO CLOCKWORK PARTS.

NO SHUNT COILS.
There's nothing in it to get out of order.

NO SPECIAL RIBBED CARBONS.
Ordinary Round Flame Carbons can be used.

ONLY ONE TYPE FOR A.C. AND D.C.
Offering great facilities for stock keeping.

Helsby Mining Accessories.

THERE is no doubt that a direction in which the application of electric power will become more and more extended, and at the same time will increase in usefulness, is in the driving of mining machinery. The strides that have been made, even during the past 12 months, in the installation of electrical machinery in mines are very great, all of which goes to show that the undoubted advantages of this class of apparatus for underground working are fully appreciated.

It may be taken for granted that the be-all and end-all of electrical working in a mine is the motor. But, in order that this may operate successfully, it is necessary that the transmission lines should be well designed, and that the intermediate apparatus, such as switches, controllers and fuses; should be capable of doing their work. This part of the scheme has been taken in hand by the British Insulated & Helsby Cables with the result that they have designed a series of excellent mining accessories.

It is only natural, before electrical working can be adopted in a mine, that supply cables must be run down the shaft. This is an operation of some difficulty not to say danger, and to minimise the attendant risks the Helsby Co. have designed the hand-driven cable winch shown in Fig. 2. The driving gear consists of a machine-cut worm and wheel and a machine-moulded spur and pinion; the worm gear prevents any possibility of the drum "running wild," and a special brake gear is therefore unnecessary. The purchase can be modified to cover a wide range of load. Current is conveyed to the cable by means of a special slip-ring collector gear enclosed in a ventilated weather-proof case. The stands are of strong construction, well stayed and bolted together, and the drums can be supplied in deal, oak, or wrought steel.

Attention may next be called to a range of three-phase joint boxes designed to meet all ordinary colliery and mining requirements. In the design and manufacture of all types of joint boxes the Helsby Co. claim they have an unrivalled

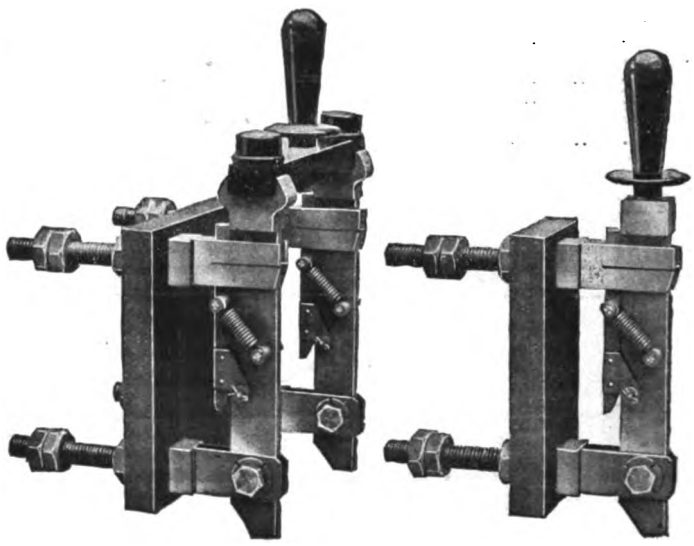

Fig. 1.—Helsby Mining Switches.

experience extending over 20 years; and although these special boxes are designed for colliery work and to meet the Home Office Regulations they are equally suitable for general use. The cast-iron boxes are gas and water-tight, and are of heavy construction to withstand rough usage. Practically all the boxes can be supplied with either a single or double bond. The single bond is intended for

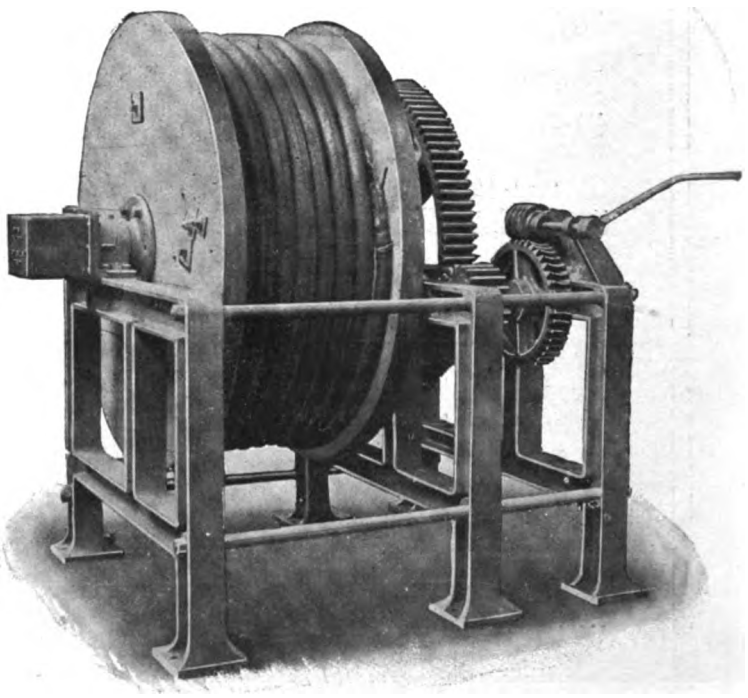

Fig. 2.—Hand Driven Cable Winch.

use with wire-armoured bitumen cables, where it is only necessary to provide a secure attachment for the armouring wires. This type can also be used with lead-covered and wire-armoured cables, and in such instances a special copper clamp is provided for bonding the lead sheathing to the cast-iron box. The double bond is, however, recom-

Digitized by Google

mended for lead-covered cables as it affords a secure anchoring for the armouring wires and positively earths the lead sheathing to the cast-iron box. The cable fittings are made

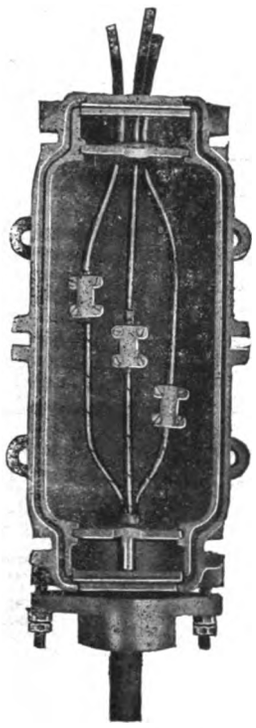

Fig. 3.—Straight Through Non-Disconnecting Box.

of copper and are of sufficient section to carry the maximum current continuously without undue heating. In all the boxes the conductors are secured to the various terminals by mechanical joints, but for non-fiery mines boxes with sweating fittings can be supplied if specified. The non-disconnecting boxes, except terminal boxes, are provided with spreaders to keep the conductors and fittings well apart; in disconnecting boxes the terminals are securely

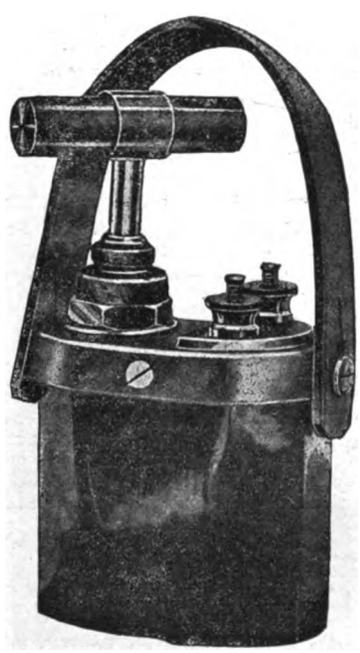

Fig. 4.—Helsby Pocket Magneto Exploder.

fixed to insulating bases, and fittings of different polarity are separated from one another and from the cast-iron box by insulating partitions. All non-disconnecting boxes should be fitted in solid with compound, care being taken that the subsequent shrinkage of the compound is made good by further pouring. Disconnecting boxes should be filled in with compound to just underneath the disconnecting terminals. To prevent sparking when making or breaking a connection, these boxes can be filled with oil above the level of the compound. Fig. 3 shows an example of straight-through non-disconnecting joint box, made in accordance with the above condition. Our illustration shows the box with the cover removed. The box is intended for use with standard size of three-core wire-armoured three-core cables, connected to the three single insulated cables. It is designed to be employed on pressures up to 3,000 volts. Fig. 5 shows a three-way disconnecting joint box for three-wire armoured cables. Two examples of Helsby switches

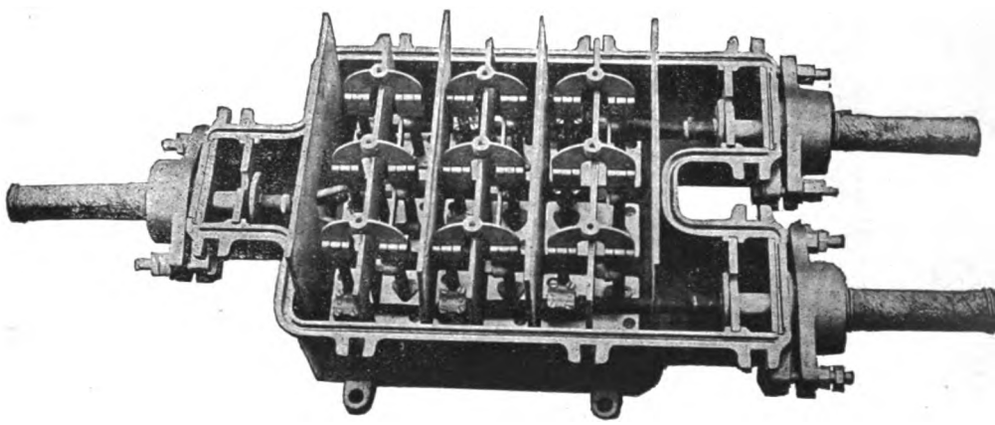

Fig. 5.—Three-Way Disconnecting Box.

for this class of work are given in Fig. 1. They are fitted with a long break and positive action, all parts of the switch carrying current being made of high conductivity

copper of ample section. The blades of the double and triple-pole switches are connected to a polished ebonite cross bar. These switches are made in several sizes up to a maximum capacity of 1,000 amperes.

In cases where several mines are fed from one power station it is becoming usual to employ overhead lines for the transmission of power. An insulator, known as the Sinclair-Aitken No. 1 leading-in insulator. is employed by the Helsby Co. It has been designed for dealing with the difficult problem of preventing leakage at points where underground cable wires are connected to open wires, or where open wires are led into buildings by means of covered wire. The inner shed, which is provided with a groove and a coarse screw thread on the outer surface, is first screwed on to the bolt and then the rubber-covered leading-in wire is laid in the groove, the outer shed being screwed on to the inner one so as to clamp the rubber covered wire in position as shown. One end of the covered wire is soldered to the line wire, the other end being connected to the underground cable or led into the building, care being taken to prevent the covered wire touching the lips of the porcelain sheds. The Sinclair-Aitken insulator is, it is claimed, not only thoroughly effective in maintaining insulation, but it has the advantage that it can be fitted and the necessary connections made by any ordinary lineman in a remarkably short time.

Fig. 4 shows a useful type of instrument known as the Helsby magneto pocket exploder. It is claimed that this type is highly efficient, and will fire two shots in series simultaneously. Further, it is compact, and is fitted with a leather carrying strap and a detachable handle. The handle is gripped in the palm of the right hand, with the stem between the fingers. The exploder is held by the left hand, and when the wires have been attached to the terminals, the action of sharply rotating the handle half a turn fires the shots. There is no key to press.

Fortiter Three-Phase Motor Starters.

IN these days of high-tension power transmission on the three-phase system it is not surprising to find that the line of least resistance is being taken, and that three-phase motors are being extensively employed. The starters for these motors require special thought and care in their design and manufacture, while at the same time they must conform to those safety conditions which are becoming more and more to be recognised as necessary in industrial electrical work. The Union Electric Co. have paid great attention to all these points.

The starters designed by them are generally intended for motors having the rotor windings connected to slip-rings. In the operation of starting, a resistance is inserted between these rings, and as the revolution rate of the motor increases this resistance is gradually cut out and the rings short-circuited. No arrangements are usually made on the standard starters for making and breaking the stator circuit, therefore it is necessary to provide in each case a switch for this purpose. The resistances are normally rated to start the motor with full load, and cannot be used for speed regulation unless specially designed for this condition. The rotor pressure—that is to say, the pressure between two slip-rings at starting—must be accurately known, so that the resistance may be correctly rated. If this information is not obtainable, the following values are assumed: With motors up to 3½ H.P. the rotor pressure will be 80 volts; up to 10 H.P., 100 volts; up to 15 H.P., 150 volts; up to 20 H.P., 200 volts.

A type of three-phase starters with the contacts and resistances under oil, and which has been specially designed for

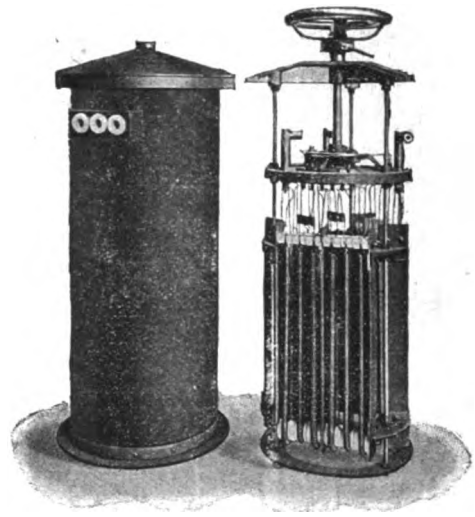

Fig. 1.—Oil Immersed "Fortiter" Starter.

use in mines, is shown in Fig. 1. These starters are enclosed within vertical cylindrical casings of sheet steel, the contacts being arranged upon slate or marble bases fixed in the upper portion of these cases and above the oil-immersed resistances. The terminals are fitted upon these bases, and the connecting cables are brought in through porcelain bushes. Access to the contacts can be obtained only after the metal covers of the cases have been removed. As with

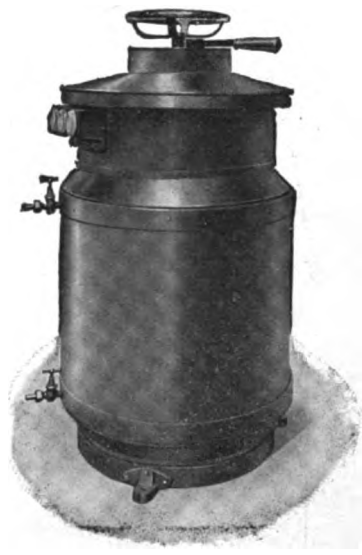

Fig. 2.—Oil Immersed and Water Cooled "Fortiter" Starter.

the smaller patterns, the starters are operated by nickel-plated hand wheels. Starters with oil-immersed resistances will carry large overload currents for short periods. In cases where the motor has been started several times in succession with short intervals of rest, it is necessary to allow sufficient time for the oil to cool down, otherwise it will reach boiling point. The resistances are rated to start

Digitized by Google

the motor under full load torque. These starters are made in 15 standards sizes, varying in capacity from 6 H.P. to 250 H.P.

Another type of starter which is intended for use where the starting conditions are extremely severe is shown in Fig. 2. The resistance is oil cooled, as before, but the starter is also fitted with a water jacket, through which circulating

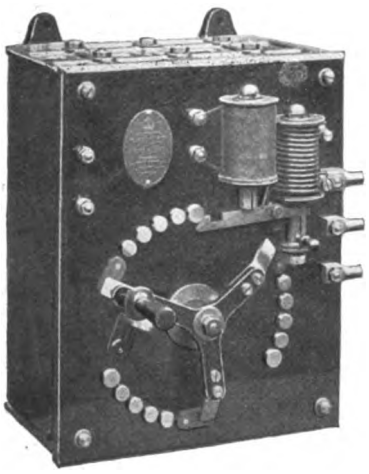

Fig. 3.—Standard Three-Phase Starter.

water can be passed. Where motors are connected to high-tension circuits suitable interlocking gear between the starters and the stator oil-break switches can be arranged.

A rather different starting equipment for use in places where protection against the surrounding atmosphere is not necessary is shown in Fig. 3. These starters are of the plain open type with black enamelled slate fronts, and starting resistance capable of passing approximately full load current on the first contact, and of carrying 50 per cent. overload for one minute or 100 per cent. for 30 seconds. They can be used in connection with any alternating-current motor having standard values of slip. They are fitted with both overload and no-volt releases, the former being placed

Fig. 4.—"Fortiter" Liquid Starter.

in the rotor circuit, which is broken on all three phases. No provision is, however, made for breaking the stator circuit, and a separate switch must be used for this purpose. The "no-volt" release acts, it is claimed, as a most efficient interlocking arrangement between the main switch and the starter, as it operates and places the starter in the "off" position directly the switch is opened.

An example of a liquid starter made by the Union Electric Co. is shown in Fig. 4. For continuous-current motors the starters are provided with two, and for two or three-phase motors with three, cast-iron tanks mounted upon a substantial cast-iron framework, and supported upon porcelain insulators. Iron plates are gradually lowered into these tanks by means of suitable worm gear, which is operated by a hand wheel. In the operation of starting the motor it is impossible in lowering these plates to exceed a certain rate. Contacts are arranged to connect metallically each plate

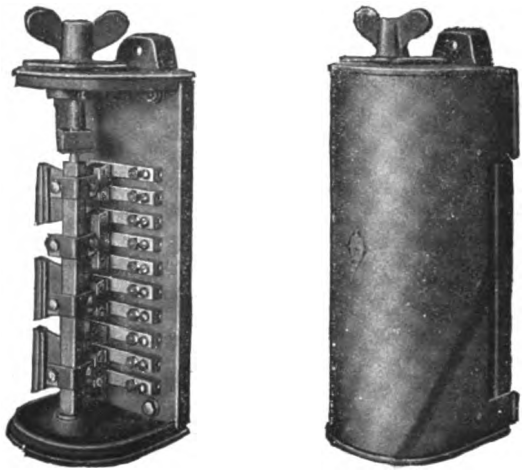

Fig. 5.—Star-Mesh Switch for Machines with Short-Circuited Rotors.

with its respective tank when the lowest or full on position is reached. The starters are designed for starting only, and not for speed regulation. The tanks should be partly filled with a solution of soda or sal ammoniac in water.

For starting such motors as have short-circuited rotors the star-mesh switch shown in Fig. 5 is used. These switches are of simple and durable construction, and suited to severe working conditions; the contacts are arranged with quick make and break to minimise sparking and consequent damage to the current-carrying parts. A ratchet device is provided to prevent the controller shaft being operated in the wrong direction. With the switches in the "off" position the motors are completely isolated from the circuits. The switches are supplied in two sizes, the larger for motors up to 20 H.P. and the smaller for motors up to 10 H.P.

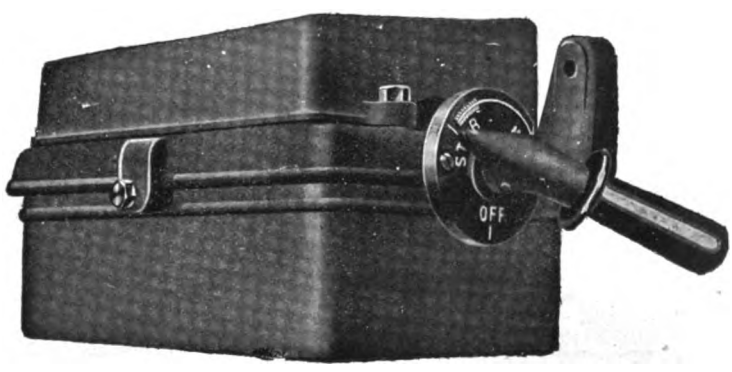

Fig. 6.—Oil Cooled Drum Starter.

Fig. 6 shows an oil-cooled starter of the drum type which can be employed with motors with short-circuited rotors.

The above description is sufficient to show that the Union Electric Co. have paid special attention to the design of starting regulating apparatus for three-phase motors. It is desirable indeed that much care should be taken in this respect for this class of motors is now being widely used in explosive places like mines, so that protection of the current carrying parts from the surrounding atmosphere is a necessity.

The ELECTRICIAN INDUSTRIAL SUPPLEMENT.
ISSUED MONTHLY with "THE ELECTRICIAN"
Telegraphic Address "ELECTRICIAN NEWSPAPER LONDON" Telephone No. 949 HOLBORN.

All communications should be addressed to the Editor, "The Electrician" Industrial Supplement, 1, 2 and 3, Salisbury Court, Fleet Street, London, E.C.

Copy for Text or Advertisement pages for next issue, publishing on **September 16th, 1910,** *should reach the above address by Tuesday,* **September 6th 1910.**

Manufacturers, Contractors, Central Station Engineers, and those interested in Electrical Industrial Developments are cordially invited to contribute original matter to the SUPPLEMENT, and when suitable this will be inserted as space permits.

Filing Case for "The Electrician" Industrial Supplement.

The INDUSTRIAL SUPPLEMENT is holed for filing, and we are distributing cases which will hold twelve issues. On request a case will be sent to Consulting, Manufacturing, or Contracting firms; to Chief or Resident Engineers of Electricity Supply, Traction or Power Stations; to any firm of Merchants or Agents; to Railway, Tramway, Dock, Harbour, or other companies interested in the applications of Electric Power, &c., to their undertakings; and to other large consumers of electrical energy, either at home, in the Colonies, or abroad.

A portion of each issue of the SUPPLEMENT is reserved for special circulation oversea.

Editorial.

The Proper Driving of Machine Tools.

There is no doubt that the proper driving of machine tools is a subject to which more attention might be paid than is at present the case. In the days when it was usual to drive one, or even more, shops by means of a single central engine a proper supervision of the power demanded was difficult, while to determine the actual amount of energy wasted in the various belts and shafting was an intricate matter. Now that the employment of the electric motor has become general, these measurements are much easier, and, owing to the subdivisions thus obtained, it is quite possible to keep a close watch on the energy consumed by the tool, and thus to nip in the bud any cause of waste that may arise. The size of motor required to drive any particular machine is too often determined in a wholly empirical manner, or from the data of past experience. While the latter of these may in nine cases out of ten give quite accurate results, yet it may happen that local conditions to some extent vitiate former conclusions and lead to mistakes being made. It is only possible to rectify such mistakes by a close inspection of the machine during operation, by taking readings of the energy consumed and thus discovering whether the tools are really working under the most economical conditions.

The results of this type of ordered inspection will be found on another page of this issue. As might be expected, they emanate from America, and while it appears that sometimes the margin of power allowed in the first instance was too large, and in others it was a minus quantity, yet in a third class there does not seem always to have been good reason why any change should have been made.

Taking the results in detail, the first is rather a glaring case, a 30 H.P. motor being replaced by a 7·5 H.P. motor. In this instance the original designers were evidently of the opinion that all the three machines would be working at full load simultaneously. This is certainly not (as it is, in fact, very seldom) the case, and the large motor has been replaced by one of only one-quarter its output. In this connection it is well to note that about one-third of the output of the new motor is taken up by driving the line shafting and in overcoming the friction of the machinery when running light. The length of shafting in this case is evidently short, but the results obtained are enough to show what great economies have been effected by the use of the divisible electric drive.

The second case is of the same *genus* as the first, but in the third, one may perhaps be permitted to wonder why it was necessary to substitute alternating-current motors for continuous-current motors of the same output. This change would certainly be viewed with disgust by some eminent engineers, and it rather seems that the change was made for the sake of changing, or perhaps with a view to obtaining certain advantages of a somewhat visionary nature. The fourth case is of the reverse kind, the motor which was replaced being overload to a small extent, but evidently sufficiently to vitiate its usefulness and make a change an economical necessity.

We need not go in detail through the remainder of the cases, for the figures are sufficient to show that the designers sometimes overshot the mark in one direction and sometimes in the other. Some of the variations are of the kind that might easily have arisen in the course of working. As the machines settle down to the work or wear their power requirements alter, while a modification in the work they have been doing would certainly be sufficient to cause the small variation in the power taken noted in some of the above instances.

The results given of this investigation tend to show that money may be saved by keeping a close watch on the energy consumed by each machine. If the power plant has been well designed in the first instance, the alterations should not need to be very severe; but there may be isolated cases where a serious slip has been made, and where a drastic change becomes necessary. This "craze for measurement" marks a step forward in workshop practice and is to be commended.

Rates and the Metal Filament Lamp.

It will be remembered that, when some three years ago the metal filament lamp was beginning to make its influence felt on the loads of electricity supply stations, certain engineers suggested that an increase in price would be necessary in order that they might preserve the soundness of their financial condition. Wiser counsels have, however, prevented this rash act, and, as far as we know, there is not a single instance of the prices for electrical energy having been raised from this cause. It does not, however, follow that the present rates are in every way the best for dealing with the new situation, and, as is well known, various attempts have been made to formulate a system of charging which shall be simple, intelligible and equitable—not at all an easy matter.

One suggestion after another has been made, among the latest being one due to Mr. S. Bingham Hood, which he brought forward at a recent meeting of the Canadian Elec-

trical Association. The system he evolves is of the differential type, and consists of three parts: A "readiness to serve" charge, a consumers' charge and a meter charge. The first of these is obtained by dividing the sum of all annual fixed and operating charges which vary with the size of the plant by the total kilowatt capacity of the generating equipment. The consumers' charge includes all those expenses which vary directly with the number of consumers connected to the system. The total of these expenses divided by the number of consumers connected to the system will give the charge, which is made to every consumer irrespective of his demand or the character of his load. The kilowatt-hour charge covers all expenses which vary directly with the kilowatt-hour output of the system. For residence lighting the demand of the consumer is arrived at by considering the floor space lighted, only that portion of the room requiring light being taken into account.

Looking at these suggestions from the English point of view, though it may be admitted that this system is equitable, it cannot be called simple, neither is it at once intelligble. It only goes to show how difficult it is to bring into the rate charged the consumer every item which goes to make up the production costs. The case is so different from that of the ordinary commodity. It is then generally easy to trace each item of cost from the producer to consumer, and to allow each such item its proper influence in the determination of the selling price. But this is not the case with the sale of "electricity."

The question then arises: Which system are we to follow? Are we to postulate that the true price "of anything is just as much as it will bring," and to charge as much, or as little, as we can get, or are we to work out laboriously the true proportion of the total cost to be borne by each consumer, and thus evolve a truly scientific rate?

If we adopt the first method we are commercial, but not scientific; while, on the other hand, the intricacies of the scientific, but complicated, system will certainly not be intelligble to the majority of consumers. On the whole, we are inclined to believe that the best way at present is to stick to unscientific methods until we have had time to educate both the public and the Board of Trade. The latter would be certain to raise objections, for it expects that consumers of the same class to be charged on the same scale, and it would be difficult to persuade them that two householders, possessing the same number of lights, but having a different area of floor space lighted, should be charged in two separate ways. While the two householders themselves might also mutually bicker.

In our opinion, then, a system of charging consisting of a fixed charge per annum, based on the consumer's maximum demand together with a charge per unit consumed, could be arranged to cover all the various items of cost met with in central station work, while at the same time the system is easily intelligible, and the variations between two almost similar consumers would not be great enough to cause any trouble.

Digitized by Google

Elliott's Instruments.

A FIRM which is well known and justly celebrated for the manufacture of instruments of all kinds is Messrs. Elliott Bros., of Lewisham. Several catalogues recently issued by this firm sufficiently well indicate their catholicity in this connection, for they include descriptions of ordinary electrical instruments of potential and current transformers, of photometers, station keepers, accelerometers, galvanometers, and distance recorders. Details of some of the equipment mentioned in this list will doubtless be of interest.

Fig. 1 shows a voltmeter of Messrs. Elliott's well-known moving-coil type, whose operation, it is claimed, is both dead beat and accurate. The pivots and jewels are carefully selected, and the springs and magnets are well aged to secure permanence of calibration. They are contained in neat japanned iron cases, and meet the demand for an instrument of moderate price yet possessing the high-class workmanship of the better form of instruments. They are made for back connections only, and are extremely useful for motor circuits, small switchboards and anywhere where space is a consideration. Every instrument is carefully checked before being sent out.

Fig. 1.—Elliott's Moving Coil Instrument.

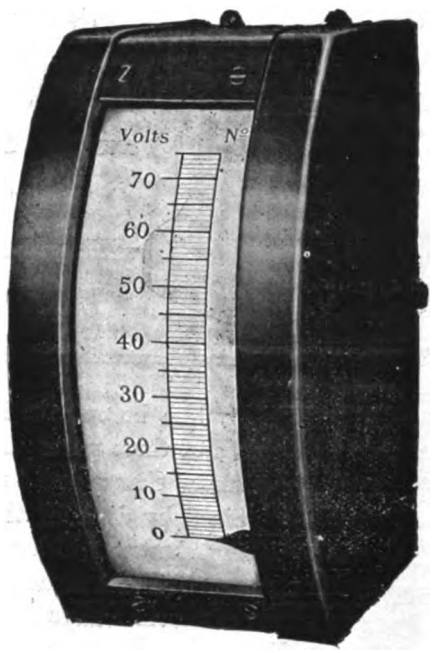

Fig. 2.—Sector Voltmeter.

Another type of moving-coil instrument of the edgewise shaped pattern is shown in Fig. 2. These have been placed on the market with a view to meeting the demand for reliable instruments at low prices, as far as is consistent with sound mechanical and electrical principles. They are contained in neat japanned iron cases without nickel facings, and are arranged either for back or front connections. The movements are on Elliott's well-known moving-coil system, dead beat and accurately balanced. The springs, pivots and jewels are carefully selected, and the magnets well aged and tested to ensure permanence of calibration. Each instrument is checked against standards, and no instrument is allowed to pass unless it satisfies the requisite degree of accuracy. Each instrument carries with it a guarantee for one year in respect of material and workmanship, and Messrs. Elliott undertake to check the calibration against their standards at any time for a period of three years from date of purchase, provided the customer pays carriage both ways.

An interesting type of portable potential transformer is shown in Fig. 3. The current transformers are of the taped coil pattern, and are mounted in teak carrying cases. They are suitable for working a maximum of two recording and three indicating instruments. The secondary or instrument terminals are provided with a short-circuiting switch, which enables the instrument to be disconnected while current is still passing through the primary winding, and prevents any risk of damage to the transformer itself by so doing. For voltages above 750 volts the transformer boxes are provided with ebonite feet, and although this is sufficient insulation in the great majority of cases, Messrs. Elliott advise that the transformers be placed upon an insulating stand or mat as an additional precaution. As in the case of the switchboard pattern current transformers, the secondary or instrument winding is the highly insulated one. Generally speaking, for currents of 400 amperes and upwards, the primary winding consists of a copper bar, but for multiple range current transformers and transformers for special requirements this is not always the case. When one instrument is to be used with several current transformers in turn, it is advisable to use a special change-over instrument switch.

The potential transformers are of the core type with thoroughly laminated iron circuits and imbricated joints. They are mounted on teak bases in teak carrying frames, the high-tension terminals being placed on the transformer base and protected by the carrying frame. The windings are of the taped pattern, and the standard secondary voltage is 100. These transformers are wound in two styles, for frequencies of 50 and 25 respectively. The 50 cycle transformers are suitable for all frequencies from 40 to 100 periods. From 39 to 23 periods the 25 cycle transformers must be used.

Another interesting instrument, which we show in Fig. 4, is the Harrison universal photometer. This instrument can be used to measure the illumination from, or candle-power, of a lamp of any nature in a test room, ordinary room or in the street. It should not be used to calibrate standard lamps, for the reason that the instrument itself depends for operation on the sub-standard lamp it contains. For practical purposes, in the hands of an intelligent operator, it can be relied upon to measure within 5 per cent. the illumination derived from, or candle-power, of any lamp.

Digitized by Google

The chief novelty of the instrument is the embodiment of a flicker disc, rotated by a blast of air under the control of the operator. This enables the instrument to measure lamps of all types of which the spectrum varies considerably, at the same time providing a light, portable and inexpensive instrument, equal in efficiency to the clumsy and expensive apparatus so far available for the purpose. The instrument is provided with a small milled head screw (painted white), accessible by opening the large side door of the photometer. By carefully turning this the flicker disc may be clamped so that one of the rotating sectors occupies half the field of view of the eye-piece, the other half of the field of view is occupied by the adjustable screen. In making a measurement by the direct comparison method, the adjustable screen is moved by means of the pointer on the left side of the case till the illumination throughout the field of view of the eye-piece is uniform. The illumination can now be read directly on the scale against the tip of the pointer. The attachment for measurement of total horizontal illumination consists of a horizontal screen of white paper having specially prepared surface, with a hole through the centre. This screen is covered with a cap provided with a bayonet joint, and when removed the white horizontal screen is exposed. With the cap in position, the arrangement forms the eye-piece of the flicker head. As before, the direct comparison of illumination is obtained against that of the adjustable screen. The instrument is arranged for two-standard

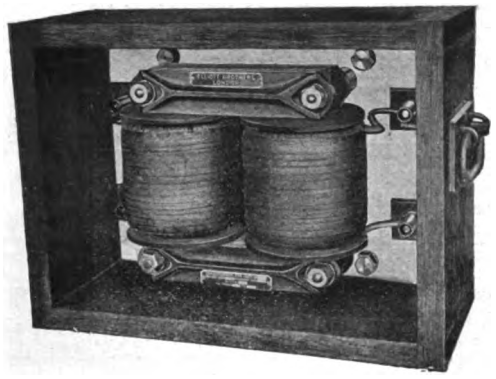

Fig. 3.—Current Transformer.

illuminations, giving two ranges, corresponding to the two scales on the instrument. Either range may be used at will by means of the two-way plug switch.

The stock instrument has scales of 0 to 0·5 and 0 to 5 candle-ft. The double range that this instrument possesses is found to be a great advantage, as it allows of measurements of illumination to be made under practically every condition. The instrument is, it is claimed, suitable not only for ascertaining the illumination due to high-power lamps in the streets and large spaces, but also when erected in offices, showrooms, &c. Moreover, it has been found that many operators can use the instrument more accurately when the screens are highly illuminated than when they are poorly illuminated, as is generally the case when making measurements at the usual distance from a street post. Thus, with a lamp giving from 50 c.p. to 100 c.p., the photometer can be erected at any convenient distance from about 40 ft. down to 4½ ft. from the lamp. Measurements at any distance from 40 ft. to 15 ft. being made with the low candle-power standard, and from 15 ft. to 4½ ft. with the high candle-power standard. Measurements can also be made consecutively with each standard to check results. The instrument is provided with a self-contained accumulator battery of two cells. This should be kept fully charged, but before taking measurements the standard lamp should be connected for about 10 minutes in order to obtain a constant potential. It is advisable to slide the battery, &c., from the case when charging, care being taken to keep the sector disc clean.

To make a measurement, the instrument is set up with the opening, with the sector disc exposed and pointing directly towards the light, so that the light falls at right angles on to the sector disc. The distance of the lamp from the disc can be measured by the knob on the side of the instrument placed there for the purpose. The sector disc can be rotated by means of the air-pressure bulb provided, and the standard lamp having been lit by inserting the plug through the hole in the side of the case, the pointer is moved until a position is found when the operator, looking through the eye-piece, can see no flicker. The pointer then indicates the illumination in candle-feet at that distance from the light, and at the angle of incidence shown by the clinometer.

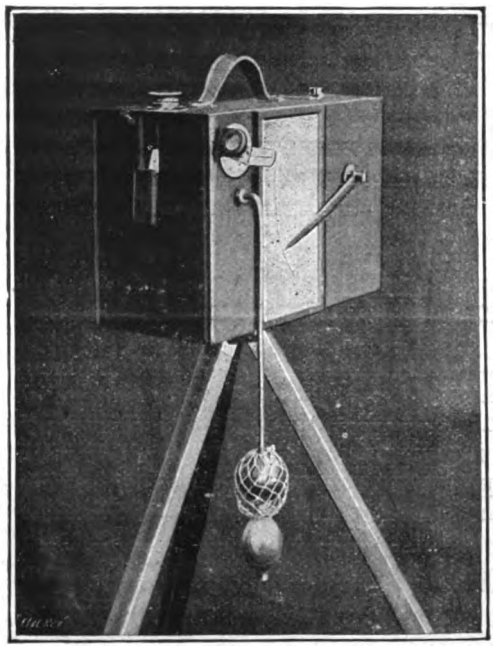

Fig. 4.—Harrison Photometer.

The Forbes distance recorder and Elphinstone speed indicator for ships is a useful instrument by which, it is claimed, the correct registration of the distance travelled by a ship can be obtained, while the actual speed in knots is indicated. The apparatus fixed in the ship consists of a sea cock or valve fitted in the bottom, preferably about one-third of the length of the ship from the bows. Through this sea cock can protrude, when indications are required, a manganese bronze tube having an opening facing forward for the admission of water as the tube is carried forward by the ship, and another opening facing aft to allow the water to escape. Between these two openings is a propeller operating the transmitting mechanism, so designed as to make a certain definite number of revolutions while the ship travels one mile. The whole of the tube which protrudes through the ship's bottom can,

OSRAM·LAMPS

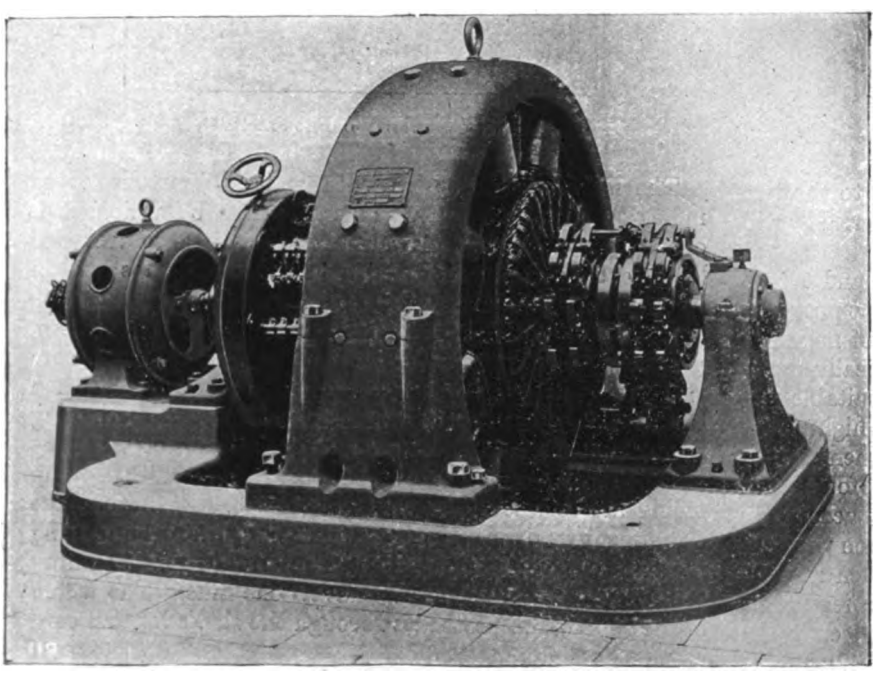
Digitized by Google

at any time, be drawn up into the interior of the ship, and then, after the sea cock is closed, the whole apparatus can be removed for examination and for cleaning if necessary. Guide rods are provided attached to the casting of the body of the sea cock to keep the tube in position when drawn into the ship, and also to keep the openings in the tube facing correctly fore and aft when the tube is pushed down.

At the top of the tube is fixed a casing, in which are two entirely separate pieces of apparatus, viz., a commutator for transmitting electric signals to the distance recorder, which is arranged so that 100 electric signals are made while the ship travels 2,027 yds., or one nautical mile; and a magneto generator, which generates current at a pressure proportional to the speed at which it revolves, this current being led to a voltmeter having its scale marked in knots, and which, accordingly, serves as an indicator of the speed of the transmitting apparatus, and therefore of the ship through the water. Both the above pieces of apparatus are driven by means of gearing from a shaft rotated by the propeller in the tube, and an arrangement of change wheels is provided so that corrections or adjustments can readily be made. It should be noted that any alteration of the change wheels affects both the distance recorder and the speed indicator, so that the indication of these two instruments maintains a consistent relation one to the other.

Vickers' Electrical Plant.

ALTHOUGH Messrs. Vickers, Sons & Maxim are known to the public at large for the work they have done in the design and manufacture of large guns, yet it must not be forgotten that they also operate in more peaceful directions and do their share towards propagating the use of electrical machinery.



350 kw. Vickers' Rotary Converter with Starting Motor.

At the Japan-British Exhibition at Shepherd's Bush they are, in fact, showing a selection of their electrical plant, among which may be mentioned a rotary converter. Its capacity is 300 kw. and its synchronous speed 750 revs. per min. when supplied with alternating current of 50. A similar set of 350 kw. output is shown in the accompanying illustration.

We may also mention a Vickers' "F" type semi-enclosed shunt-wound variable-speed motor fitted with interpoles, to give an output of 30 B.H.P. at 220 volts with speed range from 280 to 840 revs. per min., and a Vickers' semi-enclosed induction motor of the slip-ring type, which is designed to give 40 B.H.P. when running at 730 revs. per min. and supplied with three-phase current at 220 volts and a frequency of 50.

Holden & Brooke Centrifugal Pumps.

FOR many years centrifugal pumps have been used for dealing with large quantities of water against low lifts, but it is only comparatively recently that these pumps have been used to any large extent for working against high lifts. At the present time, however, they are in use for lifts equal to those dealt with by any reciprocating pump. Strength of materials is the only factor which limits the head against which these pumps can work. When it is remembered that a head of 1,600 ft. means a pressure of about 700 lb. per square inch in the pump it will beat once realised with what difficulties the designer has to contend.

As might be expected from what has been mentioned above, there has been a tendency to divide these pumps into two distinct main classes, namely, "high lift" and "low lift" types. These two classes, particularly the former, are again divided into centrifugal pumps, turbine pumps, and pumps known by their own particular trade names, but it will be seen later that although these pumps may differ very considerably in design and construction yet in principle they are all identical. It is unfortunate that such a division should have been made, for it is often the case that "low lift" is only another name for a crudely designed and cheaply made pump. Undoubtedly there is a demand for this class of pump owing to the fact that they, more often than not, form only an auxiliary part of an installation such as a circulating pump in connection with an engine and condensing plant where the initial cost is a more serious matter than the loss due to inefficiency. On the other hand, the "low lift" type also includes those large pumps, dealing with enormous volumes of water in connection with dock work, land drainage and irrigation work, in which the design, the construction and efficiency are quite equal to those of any so-called "high lift" pump.

"Single stage" and "multiple stage" would not be amuch better division, since single stage pumps have been made for pumping against heads of as much as 800 ft., and are obviously "high lift" pumps. It is preferable, therefore, not to attempt to divide the centrifugal type of pump into such sub-divisions, but rather to regard the application to high lifts as the natural development of the earlier uses.

Digitized by Google

It is not a matter of surprise that such a development should have taken place in these pumps, for they possess many advantages over other types. The initial cost is low, and at the same time good efficiencies can be obtained, as will be seen from the table given below, which shows the relative prices of, and power required to drive, a few actual reciprocating and centrifugal pumps.

Centrifugal pump and motor.				Reciprocating pump and motor.	
Gallons per minute.	Head in feet.	H.P.	Price.	H.P.	Price.
			£		£
167	750	60	280	55	510
300	400	52	180	55	480
300	100	14	110	20	310
700	607	190	390	180	1,640

The number of wearing parts is small. They are suitable for dealing with water containing solid matter in suspension as they have no valves. The high rotative speed necessary makes direct driving by electric motors an ideal arrangement. The space occupied by the plant is small and only light foundations are required. Transport and erection are comparatively small items.

Much use has been made of this type of pump in the unwatering and drainage of mines. The small space occupied by a pump and motor capable of dealing with large quantities of water, the ease with which power can be conveyed to the electric motor and the fact that only one pipe—the delivery pipe from the pump—is required, make them admirably suitable for slinging in mine shafts.

A firm who have paid great attention to the design of these pumps are Messrs. Holden & Brooke, of Manchester. The shaft inside their pump is completely covered either by the impellers themselves or by gun-metal bushes, thus preventing any corrosion taking place. The end thrust, and in the case of a vertical pump, the weight of the impellers and shaft, is completely balanced hydraulically and automatically, thus absolutely dispensing with thrust bearings of any description. The pressure on the back of the last impeller is automatically regulated to that required to balance the end thrust by allowing the shaft with its impellers and a balance valve to have a slight end movement which, in actual operation, enables it to take up such a position that the amount of leakage past the face of the balance valve is of such an amount that it requires the necessary pressure on the back of the impeller to force this water past the small orifice shown in the flange of the delivery end bearing. The amount of water required for balancing does not exceed a fraction of 1 per cent. of the total amount passing through the pump. It will be noticed that this design of balancing arrangement is independent of any wear which may take place on the face of the balance valve, and, as wear takes place on the impeller neck rings the amount of balance water required actually decreases. It should also be noted that the delivery end bearing, the balance valve, and the renewable valve seating ring can be taken out of the pump without disturbing the main bodies or the pipe connections.

The pump is fitted with the necessary air-cocks, drain cocks, priming cock and tundish. Provision is made on the suction and delivery branches for attaching gauges which are supplied as extras. Owing to the special design of covering which is cast with the bodies the pump presents, it is claimed, a neat external appearance without the use of any sheet metal covering, which soon becomes rusted and damaged.

Recently much stress has been laid upon the value of pumps giving a so-called "self-regulation" when working with varying heads. The effect of this is that the power required to drive a pump running at a constant speed does not exceed a certain limit, however much the head is reduced. Undoubtedly cases arise in which it is beneficial to instal pumps having this property of self-regulation, as for example in sinking or unwatering mines. It should be borne in mind, Messrs. Holden & Brooke point out, however, that in all cases this property is obtained at the expense of efficiency at the normal duty of the pump. This must be so from the very nature of the method by which the self-regulation is obtained. Although one pump *without* self-regulation may have a maximum efficiency of, say, 65 per cent., while another of a different size *with* self-regulation may have a maximum efficiency of 70 per cent., yet of two pumps built on the same lines, for the same output, the one *without* self-regulation would have the higher efficiency when dealing with its normal output. It will be seen, therefore, that this property has its limitations, and that whereas in some cases it may be desirable to make use of it, in other cases, where the head is practically constant, it is preferable to instal pumps without self-regulation in order to obtain the maximum efficiency under the normal working conditions. The effect being obtained by means of impellers specially designed but without small nozzles, which are so liable to become choked up when dealing with dirty water.

"Tricity" Cookers.

ALTHOUGH the present summer has not provided any days of very great heat, the weather has been sultry enough to justify the claims made for electrical cooking apparatus as regards its hot weather advantages. Not only is electrical heating simple, easily regulated and perfectly controlled, but the heat produced therein is localised and applied just where it is wanted, and does not heat the surrounding atmosphere.

A cooker for which all these advantages are claimed is that known as the "Tricity," made by the Berry Construction Co. Fig. 1 shows a "Tricity" duplex cooker, from which it will be seen that the body of the cooker is surmounted by a circular iron plate. This plate, on which the various utensils are placed, is raised to a dull red, or lesser heat, which is controlled by means of two switches. One switches the current "on" or "off," the other regulates

Digitized by Google

the temperature to "high" or "low." The handle of the switch indicates its position, and when pointing to "low" the heat obtained is one-quarter of that when the handle points to "high." Current is brought to the cooker through a flexible steel-covered cable, thus ensuring, it is claimed, absolute safety. Three types of cookers are made: The duplex, with two hot plates; the single, with one hot plate; and the extension, also with one hot plate. This latter is intended for use as an extension to the duplex cooker, or for

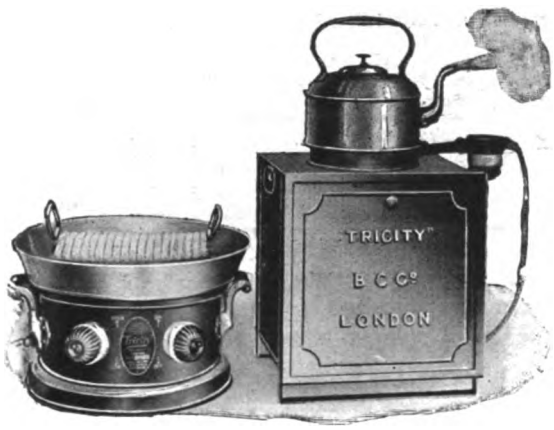

Fig. 1.—No. 1 "Tricity" Range.

oven top heat with single and duplex cookers, or again, it is useful alone for boiling, stewing and similar simple operations. The combination of the duplex with one or more extension plates provides a wide range of utility, and permits a variety of cooking processes to be carried out simultaneously.

The oven is made in two sizes, and is placed on the top of the cooker, so that the hot plate projects into the oven. To obtain a top heat, so essential for browning purposes, the extension cooker is inverted and placed on the top of the oven, with its hot plate projecting into the oven. An oven

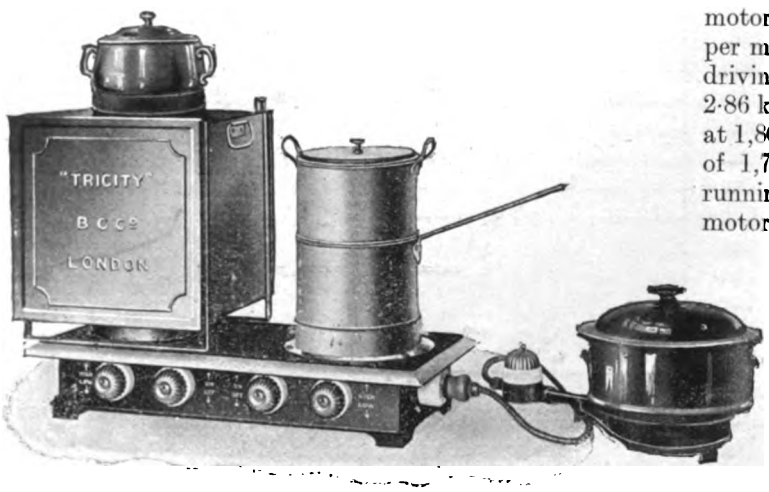

Fig. 2.—"Tricity" Range.

set on the table with the extension plate arranged for top heat only forms a useful hot cupboard for keeping food warm, or warming plates, &c.

Special grills, saucepans and other appliances have been designed and arranged for use with the "Tricity" cooker. To all outward appearances they are, with the exception of the grill, exactly similar to the utensils to which you are accustomed, but special care is taken with every one to make the bottom as flat as possible, so as to obtain good contact with the hot plate of the cooker, and so, by avoiding loss of efficiency, make the cooking rapid and economical. The utensils cost only a few shillings each. There are no wires attached to any of them, the only wire is the steel-covered one previously referred to, attached to the cooker. No harm can come to the cooker by being left "on," and whether there are any utensils on it or not there is, it is claimed, nothing to destroy or to burn. Of course, "Tricity" utensils will no more stand being boiled dry or used empty without suffering than the utensils in use on any kitchen range, but if they are destroyed accidentally, or through carelessness, it is only a matter of a few shillings to replace them, and no damage will have been done to the cooker.

Re-Powering Machine Tools.

ONE of the greatest advantages of the electric drive is the facility with which the power requirements of different tools and machine combinations can be tested from time to time for the purpose of securing the most positive and efficient operation of the plant. By means of a few electrical measurements data may readily be secured to determine the power necessary to operate the machine. In the following paragraphs which are taken from the "Electrical World," are given the results of a number of tests of this kind in a large foundry, with the changes determined by simple voltmeter and ammeter readings. The data illustrates the need of going over machine-tool installations from time to time to find out whether the conditions of power supply and utilisation require a readjustment of the motors in relation to the tools, a substitution of group for individual driving, or vice versa.

All motors in service were of the direct-current type, wound for 500 volts, and were replaced by 550 volt three-phase motors. One 30 H.P. motor, running at 650 revs. per min., driving a line shaft and three rattlers, light took 2·2 kw.; driving one rattler loaded it took 3·5 kw. The motor was replaced by a 7·5 H.P. motor running at 1,200 revs. per min. One 7 H.P. motor, running at 950 revs. per min., driving a suction fan for rattlers, with the usual load, took 2·86 kw. The motor was replaced by a 5 H.P. motor running at 1,800 revs. per min. One 3 H.P. motor, with a rated speed of 1,700 revs. per min., driving a sand conveyor, when running unloaded took 0·9 kw. A 3 H.P. alternating-current motor, running at 1,800 revs. per min., was substituted for this motor. One 2·5 H.P. motor, with a rated speed of 1,620 revs. per min., driving a double grinder, with the grinder idle took 0·68 kw., with the motor driving the grinders, two men grinding light castings, it took from 1·1 kw. to 1·8 kw. A 2 H.P. 1,800 revs. per min. motor was substituted. One 2 H.P. motor, running at 1,280 revs. per min., driving a 36 in. exhaust fan, removing gases from the core room and ovens, with normal load took 1·8 kw. It was replaced by a 3 H.P. motor running at 1,800 revs. per min. One 5 H.P. motor running at 1,200 revs. per min., driving a sand mixer, when running light took 0·92 kw.; and when running loaded took 1·84 kw. This motor was replaced by a 4 H.P. 1,200 revs. per min. alternating-current motor.

One 2·5 H.P. motor running at 1,700 revs. per min., driving a rattler, when running light took 2·2 kw. A 3 H.P. 1,800 revs. per min. motor was substituted for this motor. One 40 H.P. six-pole motor, rated at 975 revs. per min. when running light and at 840 revs. per min. when loaded, driving a Roots blower, one hour after starting took 0·26 kw. A 35 H.P. 900 revs. per min. motor was substituted for this

Digitized by Google

motor. One 2·5 H.P. 1,800 revs. per min. motor, driving a 36 in. band saw, a 14 in. bench saw and a 7 in. lathe showed the following conditions: Motor driving shaft light took 0·66 kw.; motor driving band saw, 2 in. pine stock, took 1·1 kw.; motor driving band saw, with 2 in. plank on bench saw, took 3·3 kw. This load was so excessive that motor speed was reduced to 70 per cent. of normal speed. The motor was replaced by a 5 H.P. 1,800 revs. per min. motor. One 2 H.P. motor was running at 2,000 revs. per min. connected to a 3 in. by 24 in. planer. This motor was unable to plane wide stock at the desired speed. It was replaced by a 5 H.P. motor running at 1,800 revs. per min.

B.T.-H. Motors and Generators.

THE latest type of continuous-current motors and generators made by the British Thomson-Houston Co., of Rugby, embody some new features in their design, though the construction of this class of equipment has become so standardised that it seems that little more can be done, except in improving comparatively minor details.

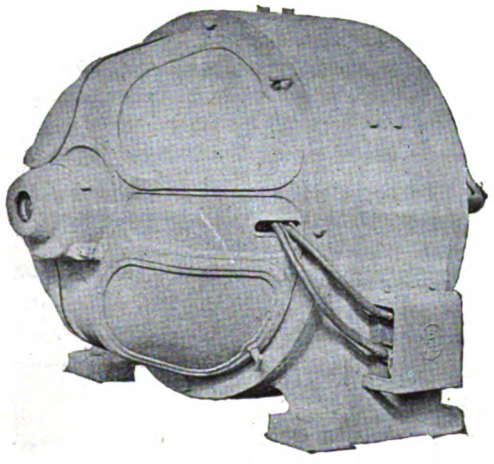

Fig. 1.—B.T.-H. Motors with Solid Covers.

Turning to the details of these motors, which suffice to show how certain excellent results are obtained, only the best quality of material is used in the insulation of the armature and field coils. Special attention is given in the process of manufacture to the removal and permanent exclusion of moisture from the insulating material of the coils. To this end the insulated conductors of which the coils are formed are subjected to a drying process and then treated with a special moisture-proof compound. The coils are subjected to a high potential test of alternating current at a pressure of 1,500 volts applied between the coils and frame for a period of 60 seconds while the machine is hot.

The core consists of laminations of sheet steel of high permeability slotted on the periphery to receive the windings, and clamped under pressure between substantial end flanges. To minimise losses due to eddy currents the laminations are coated with an insulating compound before assembly. The cores are provided with radial ventilating ducts to allow of the free circulation of air through the body of the armature. At the ends of the armature, and also in each ventilating duct, steel spacers are provided to support each tooth. This construction, it is claimed, prevents the vibration which may occur with unsupported teeth.

The armature consists of form wound coils which are carefully insulated and then inserted in the slots of the armature core, which are insulated to receive them. The coils themselves consist of high conductivity copper conductors, and are secured by binding bands calculated to resist the centrifugal force at the maximum speeds with an ample factor of safety.

Fig. 2.—B.T.-H. Protected Motor.

The commutator is built up of hard-drawn copper segments of ample wearing depth insulated from one another by means of carefully selected mica, and from the clamping rings and shell by means of cones and a sleeve of specially prepared mica. The commutator shell is forced into position and rigidly keyed to prevent any relative movement between the armature winding and the commutator. The commutator shell is provided with ventilating ducts and the commutator has ample cooling surface.

THREE-PHASE
AUTO-TRANSFORMER
STARTERS.
TOTALLY-ENCLOSED. 245

Digitized by Google

The magnet frame is of cast iron, and has inwardly projecting poles rigidly bolted thereto. The main poles are built up of laminated steel, and can be removed with the field spools without any displacement of the armature being necessary. The field coils are wound on substantial bobbins and are held in position by means of the projecting pole-tips. They can be readily taken off when the poles have been removed from the frame.

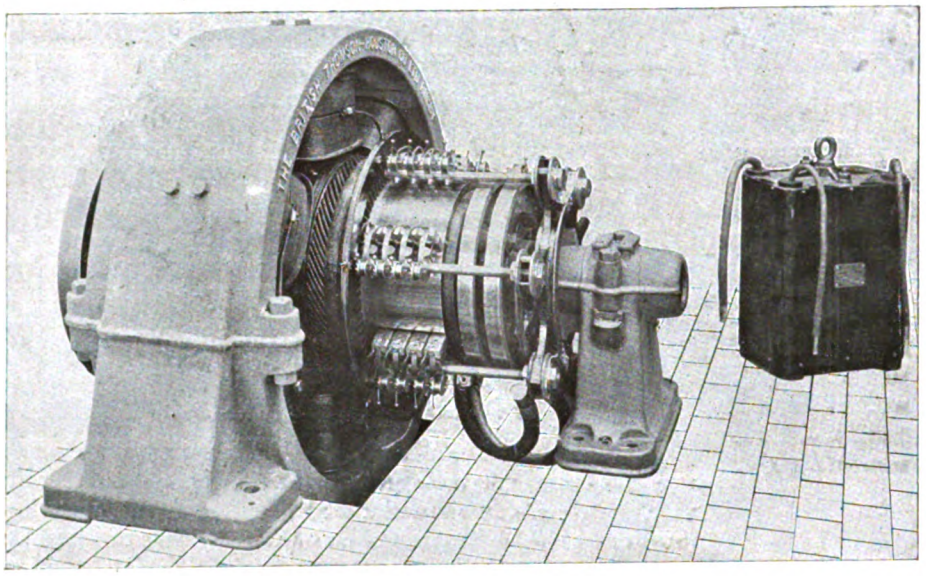

Fig. 3.—Three Wire Generator with Neutral Compensator.

The bearings are carried either in end shields, or in pedestals when such are required. In the former case a special mechanical feature is the provision of adjusting screws on the end shields, by which the bearings can be readily re-centred when it becomes necessary; this re-centreing can be done on belt-driven machines without removing the belt. In the former case the bolts are so spaced that the end shields and bearings can be turned through 90 deg. or 180 deg., thus allowing the motor to be mounted on the floor, wall or ceiling. Standard slide rails

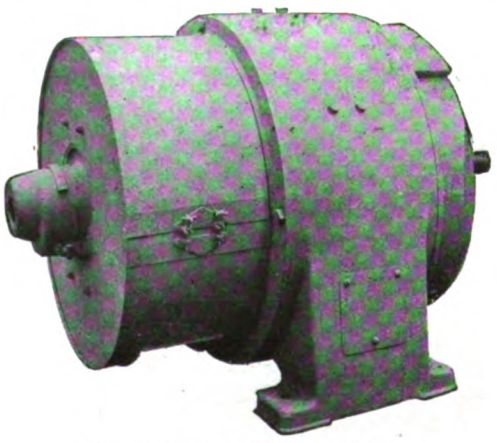

Fig. 4.—Totally Enclosed Motor.

are suitable for floor use only. For ceiling or wall suspension special rails will be required. The bearings are of the self-oiling type, the lubrication being effected by means of loose rings on the shaft dipping into large oil wells. The bearings are of cast iron with linings of white metal and are self-aligning. The length of bearing is three times the diameter of the shaft.

The brushes are of carbon and are carried in brush holders of the clock spring type, so constructed that the tension of any brush is uniform throughout the life of the brush, and is readily adjusted without removing the brush from the commutator, and without the use of any tool. Any brush can be removed while the machine is in operation without disturbing the others and without removing the holder from the stud. Flexible connections are employed for carrying the current direct from each carbon brush to the body of the holder, thus making a positive connection between the two. The brush studs are securely locked to prevent rotation due to vibration.

All these B.T.-H. machines will stand full load for six hours with a temperature rise (by thermometer) not exceeding 40°C., and will stand 25 per cent. overload for one hour and 50 per cent. momentarily, without injurious heating or sparking. The temperature rise, measured by thermometer, is based on the assumption that the mean temperature of the surrounding air (measured within 3 ft. of the machine) does not exceed 25°C. If at the time of test the mean temperature of the surrounding air is higher than this temperature, the observed temperature rise on the machine must be reduced by ½ per cent. for each degree centigrade, the mean temperature of the surrounding air exceeds 25°C.

As regards speed regulation, stand and shunt-wound machines without commutating poles may be increased in speed up to 5 per cent. above the normal by varying the excitation and without causing injurious sparking. If a greater speed variation than this is required commutating poles must be used. This variation of B.T.-H. motor is wound for the standard voltages of 200, 220, 250, 400, 440, 500 and 530. The accompanying illustrations are examples of the types made.

Electricity in Excavation Work

AT the present day, when the time which is allowed for construction work must be reduced to a minimum, electricity is finding a wide application, due to its inherent advantages, and in many places the electric motor is supplanting the steam engine. Electrical apparatus is especially serviceable to contractors, and will be found to result in a great saving in time and money. The electrical equipment is always ready for instant use, thus eliminating the loss of time in getting up steam when a steam engine is used.

Its use results in a reduction of expense, as one pays only for the power which actually does work. There is no consumption of power when the motor is not in operation. This eliminates the expense resulting from the consumption of fuel in order to keep up steam while the equpiment is not in operation and to enable work to be resumed at any desired moment. Any person of ordinary intelligence can operate an electrical equipment, and thus the high wages of a licensed engineer are saved.

The operation of an electrical equipment is not attended with objectionable and annoying features. There is no fire hazard due to flying sparks or live coals accidentally dropped from the boiler fire box, nor is there the nuisance

Digitized by Google

of smoke, ashes and dust. The operator is not burdened with the responsibility of keeping sufficient water in the boiler, maintaining a hot fire to keep up steam, shovelling coal, removing ashes, &c. Its use eliminates the danger of water pipes and cylinders freezing and bursting in the winter time.

It is a very simple matter to instal it, and it can be changed from place to place at will Its position is not determined by features which limit its installation to certain points, as in the case of the steam-driven equipment, where steam or water supply pipes limit its location. After it has been moved to its new position the wires can be readily changed.

A good example of the use of electricity in contracting work is the recent work on the Champlain Barge Canal, which has been recently described in the "Electrical Review and Western Electrician."

This installation is unique in being one of the first to be equipped with induction-motor drive, and also to employ dynamic braking. The bucket is controlled by two cables, which are operated by a double-drum hoist. This double-drum hoist is driven by a 90 H.P. 550 volt high-torque three-phase induction hoist motor working at a frequency of 40. The excavator is mounted on a circular track permitting its rotation through a complete circle, and making it possible to dump the bucket wherever desired within quite a large radius. The hoist for accomplishing this movement is driven by a 22 H.P. 550 volt high-torque three-phase inductionhoist motor.

The controlling apparatus consists of a group of contactors, interlocks, current-limit relays and a motor controller for the operation of the main drum hoist motor and the control of the speed of hoisting and excavating by a varying resistance inserted in the motor circuit. This type of control, known as magnetic control, is essential in work of this class owing to the severe conditions. The operator is able to give a jerky movement to the bucket in order to shake clay and sticky mud from its bottom.

The motor is protected from overloading by a triple-pole circuit-breaker adjusted to trip at about 50 per cent. above normal full-load current. This protection is necessary, since the bucket may strike a rock or other hard substance embedded in the soil being excavated. The motor which rotates the excavator is also protected by a triple-pole circuit-breaker, and is controlled by a drum-type controller with a bevel gear and lever device instead of the ordinary handle.

The two drums for hoisting and digging are each provided with an air brake for retarding the movement of the bucket or boom when these are being lowered. This equipment consists of an air compressor of 19 cub. ft. displacement driven by a 6 H.P. 550 volt induction motor, and controlled by an automatic pressure governor which starts the motor when the pressure falls below a certain value. As soon as the required pressure is restored, the controller automatically stops the motor. For controlling the air brakes two valves of the type designed for electric car service are provided.

Two of these excavators are employed. Power at a pressure of 6,600 volts and a frequency of 60 cycles was purchased from the Hudson River Power Co. and stepped down to 550 volts for operation of the motors by a bank of three 60 kw. transformers.

A triple-pole oil switch and a lightning arrester, both designed for operation on a 6,600 volt system, are installed in the temporary building beside which the transformers are located. The transformers and buildings are mounted on skids to facilitate moving the apparatus as the work progresses.

W. & W. Motor-Generators.

A WELL-designed and built series of motor-generators, by which one continuous current can be transformed into another of either higher or lower voltage are now being made by Messrs. Wright & Wood. A variation of the generator voltage is provided, the set consisting of two direct-coupled shunt-wound machines mounted on cast-iron bed-plates.

The bearings are of the journal type and are provided with automatic oil ring lubrication. Both field and armature windings are of the interchangeable former type, and before mounting are vacuum dried and impregnated with the best insulating varnish, thus ensuring, it is claimed, complete immunity from breakdown. All insulating material is of the best quality and ample ventilation is provided. Carbon brushes only are employed, and the machines are so proportioned that absolutely sparkless running is secured. Mechanical balance and freedom from vibration may be mentioned as noteworthy features. All openings in the machine can be provided with ventilated covers if required, and all terminals are protected by a cast-iron cover. The temperature rise on load does not exceed 75°F. after a six hours' run.

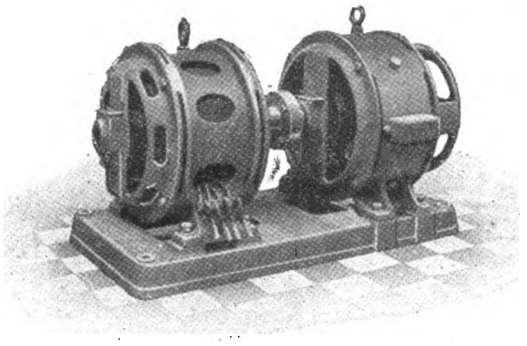

Fig. 1.—W. & W. Motor-Generator

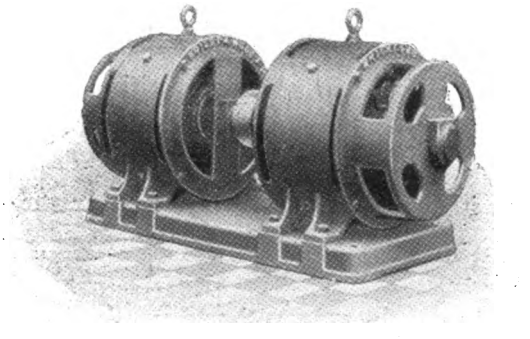

Fig. 2.—Another View of the same Machine.

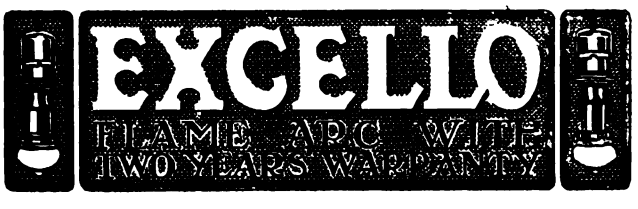
The overall efficiency varies from 42 per cent. for the 240-watt set to 85 per cent. for the 25 kw. size.

Induction motor-generators are also made and these transform single, two, or three-phase alternating current to continuous. The motors are all of the squirrel-cage type, wound for a frequency of 50, but other frequencies can be



Digitized by Google

adopted when necessary. The efficiency of the two and three-phase sets is equal to that of the continuous-current type, but the single phase is 10 to 15 per cent. less. No brush gear of any description is required on the motors, which are of the most substantial design.

Single field motor transformers for direct current only, in outputs varying from 0·9 to 5·75 kw., consist of a standard magnet frame and an armature provided with high and low-tension windings and two commutators. These machines have a higher efficiency than the motor-generator sets, but the voltage on the generator side cannot be varied, having a value in fixed proportion to the supply voltage. Rotary transformers for converting direct to alternating single, two or three-phase current are also a speciality with Messrs. Wright & Wood, and can be supplied to specification.

Star Delta Switches.

A SERIES of oil-break switches entitled as above are now being placed on the market by Messrs. Siemens Brothers Dynamo Works. They are of the oil, immersed drum type, and may be used for currents up to 50 amperes at 3,300 volts, 100 amperes at 2,200 volts, and 300 amperes at 650 volts.

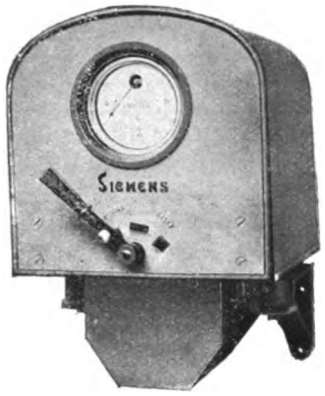


Fig. 1.—Star Delta Switch with Ammeter arranged for Wall-Fixing.

A stop is provided at the star position to prevent the switch from over-running this position, and to allow the motor to attain a suitable speed before switching in to the delta position. It is impossible to put the switch into delta position without previously passing through star position. Provision is also made to prevent the switch from being left in any but the delta or off positions.

Fig. 2.—Star Delta Switch with Cover removed.

Fig. 3.—Star Delta Switch arranged for Floor-Fixing.

When the switch is in the off position the motor is completely cut off from the mains.

The contact fingers are made adjustable to ensure a good contact pressure between them and the contact rings on the drums. The copper contact rings are mounted on insulating discs carried on the drum shaft. The terminals consist of copper rods carried through porcelain insulators, the latter being cemented to the cast-iron top-plate of the switch. If desired, special protected terminals encased in fibre tubes can be supplied. The sheet-metal oil tank may be readily removed for inspection of the drum and contact fingers. These switches can be supplied non-automatic suitable for wall fixing, or automatic, fitted with overload and no-voltage releases, suitable for either wall fixing or floor fixing; in the latter case, tubular columns are provided through which the cables may be led to the switch.

The amount of oil required for these switches is $2\frac{1}{2}$ gallons, the weight being $8\frac{3}{4}$ lb.

Renold's Silent Chain.

A VERY useful method of driving machinery is that due to Messrs. Hans Renold (Ltd.) The original silent chain, of which system we speak, was introduced by Mr. Hans Renold in 1895, and while the principle of the gearing has remained unaltered there have naturally been many changes in the construction. The first chains were made up of thin plates threaded alternately right and left

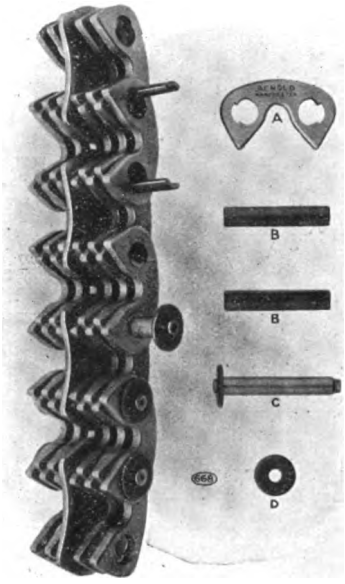

Fig. 1.—Liner Silent Chain.

on to hardened studs. The bearing surface on each side of the stud was thus only half the stud length and was broken up into a number of separate bearings, each as long as the thickness of the plate. These plates could not be hardened and the wear on the chain joints was found to be very considerable. In 1900, an improvement was made by placing several plates together and inserting hardened bushes in the end holes. In this way increased durability was obtained on the wearing surface, but there were certain difficulties of manufacture, so that this type was eventually succeeded by the block silent chain. In this new idea hardened blocks ranging from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. wide were used instead of groups of bushed plates. This pattern was very durable, but was not so strong as the earlier arrangement, as the blocks were sawn from drawn steel bars, which were necessarily milder than the rolled strips from which the thin plates were punched. Experiments then led to the introduction of the patent liner silent chain, which was introduced in 1904.

LEWIS'S SCIENTIFIC CIRCULATING LIBRARY.
ELECTRICAL, MECHANICAL & GENERAL ENGINEERING TEXT BOOKS & TECHNICAL WORKS.
New Works and New Editions can be had from the Library immediately on Publication.
SUBSCRIPTION, Town or Country, from ONE GUINEA. READING ROOM open Daily to SUBSCRIBERS
136, GOWER St., & 24, Gower Place, LONDON, W.C.

The new feature of this arrangement was the introduction of hardened segmental liners at the chain joints. These are fixed in the chain plates and give an increased and continuous bearing on the pins. This chain is shown in detail in Fig. 1. The liners are fixed in the plates and bear on the studs. They extend over the whole width of the chain and consequently the wearing surfaces obtained are the maximum possible, while the wear of studs is evenly distributed owing to their freedom of rotation. These bearings can be easily lubricated as the spaces between the liners allow the oil to reach the bearings readily. Each hole in the plate has one small and one large recess the small gripping the liners and the large ones giving them clearance, and so allow the plates to swing on the studs. In a new series of liner chains, made with thick plates, the shape of the hole has been improved, so that the chain can now be bent almost as far backward as forward. This arrangement is shown in Fig. 2. An inner and outer combination of plates is thus formed at each joint and the

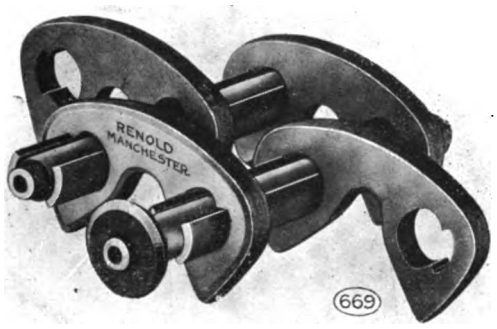

Fig. 2.—Skeleton showing construction of Liner Silent Chain.

liners in one combination can move through the clearance recesses of the other sufficiently to allow the chain to encircle the smallest sprocket used. The liners, being at the outer ends of the plates, bear on the studs when the chain is in tension.

In 1909, owing to the difficulty of manufacturing the patent liner silent chain in very small sizes, Messrs. Hans Renold again introduced the principle of the old bushed link silent chain mentioned above. The new chain is made from single plates of heavy gauge instead of groups of thin plates, the holes being lined with glass-hard circular bushes. This chain is shown in Fig. 3. The bushes are slightly longer than the thickness of the plates and project a little on each face of the latter, and so prevent them from binding against each other. This reduces the bending friction to a minimum and considerably improves the lubrication. It is pointed out that since the bearing surfaces of the points are well hardened the chain is very durable, and the little wear which takes place is evenly distributed owing to the studs being free to rotate.

The type and size of chain to be used depend on a number of considerations, viz.: Nature of the drive—whether the load is steady or impulsive, &c.—the speed required, the power to be transmitted, the relative position of driver and driven shafts, the shaft centre distance, the speed ratio and other more general conditions.

About 1,300 ft. per minute is a normal maximum speed for silent chains up to 1·5 in. pitch inclusive, and 1,200 ft. per minute for larger sizes. These speeds may, of course, be exceeded, but then it is advisable to provide an oil bath chain case, especially with the larger chains, and to erect the gear very substantially. With these provisions, though at the cost of reduced life, silent chains may be run up to 1,800 ft. per minute in the smaller sizes and 1,500 ft. per minute in the larger.

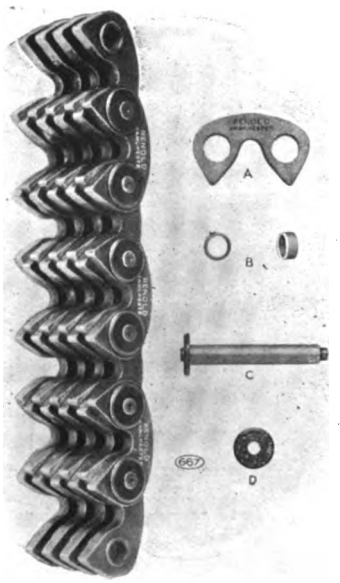

Fig. 3.—Bush Silent Chain.

The factor of safety may vary from 30 for 1·75 in. pitch chains to 50 for 0·5 in. pitch chains at the maximum speed. These factors are not needed to ensure safety but to obtain a reasonable bearing pressure on the studs. As regards the position of drive, inclined or horizontal positions, with the tight side of the chain on top, are the best. When the slack side is above, the action on the small wheel is not quite so smooth. If a vertical position is necessary, adjustment of the centre distance is very important and must be carefully attended to, as otherwise the chain may fall out of gear with the lower wheel.

The normal minimum distance between the shafts should be equal to 50 pitches of the chain used; it would thus be 4 ft. 2 in. for a drive using 1 in. pitch chain. The distance may, however, be reduced until the wheels only just clear, but the life of the chain decreases out of all proportion to the decrease in centre distance. Greater distances than the minimum are advantageous, as they give more chain over which to distribute the wear. The maximum centre distance is about 15 ft. to 20 ft., but, on account of the weight of the chain between the wheels, it largely depends on the rigidity with which the gear is mounted.

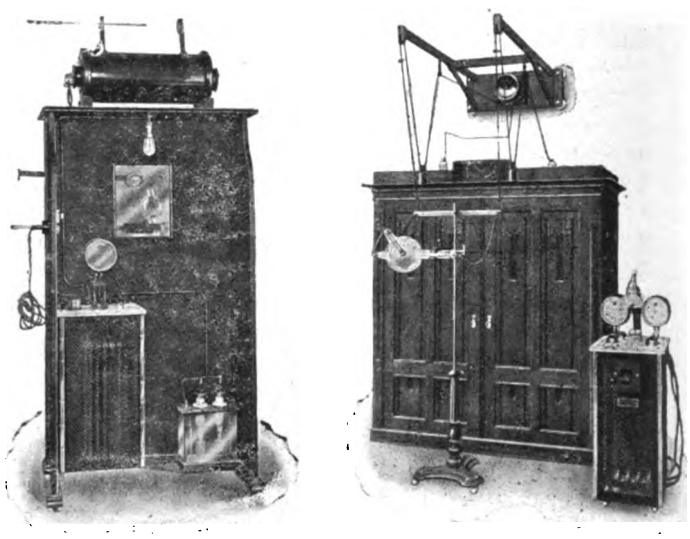
Wherever possible some means of adjusting the centre distance should be provided. Slide rails are not always necessary, although they are very convenient; for motor to lineshaft drives, adjustment may be obtained by means of packings or slotted holes in the motor feet. A short or vertical drive requires nicer adjustment than one running in an oblique or horizontal position, where the chain acts to a certain extent as an automatic adjuster. This is, however, insufficient if the centres are short and the load impulsive, and in such cases if adjustment of centre distance is not possible, it is necessary to fix a jockey wheel on the slack side of the chain. The jockey is an ordinary chain wheel as large in diameter as possible, and must gear with the inside of the chain, thus forming a triangular drive. It must further be placed in such a position that at least three teeth mesh with the chain. A jockey wheel must on no account be used on the back of a chain. It burrs over the edges of the links, making the joints stiff, and may also bend the chain backwards at a sharper angle than is permissible with the liner type chain. The chain should be run at a tension which would be considered just too slack for a leather belt, the correct adjustment allowing it a slight sag.

The silent chain gear is, it is claimed, a well-finished and accurate piece of mechanism, and to obtain the best results must be carefully erected. Although the chain has a certain amount of lateral flexibility, and gives satisfaction where the conditions are far from ideal, as on motor cars, erection cannot be too substantial if the maximum life is to be obtained. Shaft bearings should be rigid and sprockets should run true, and be mounted near a bearing if on light shafts liable to spring under load. If the drive is from an electric motor the end-play of the armature shaft must be kept down to a minimum, say from $\frac{1}{16}$ in. to $\frac{1}{8}$ in., according to the centre distance of the wheels and the size of the chain. Greater exactitude in alignment is necessary than with belts. It is not sufficient that the chain is running centrally on both driver and driven wheels, as this result could be obtained by a combination of disalignment in two planes, and yet the chain might be racking itself to pieces. The shafts must be both level and parallel and the wheels should be tested for alignment. Whilst the setting up of chain drives does not require the degree of accuracy necessary for double helical spur gears, it is not too much to say that fully three-fourths of the failures of silent chain drives have been due to faulty alignment, generally aggravated, it is true, by insufficient lubrication. Of the remainder, lack of lubrication alone, Messrs. Hans Renold consider, accounts for the greater part.

Siemens Electro-Medical Apparatus.

THE subject of the application of electricity to medical work has lately been brought prominently before the public by the death of Mr. H. W. Cox. Mr. Cox, like many others, was the victim of ignorance of the conditions under which the X-ray works, and through his experience it has been possible to devise apparatus for the prevention of like disasters.

Messrs. Siemens Bros. & Co. are a firm who have paid a great deal of attention to this class of work, and the apparatus shown in Fig. 1 represents a complete outfit with 16 in. spark induction coil, switch table and Wehnelt interrupter. The apparatus is arranged on a protecting screen. In fact: in order to avoid the harmful effect which may be produced by frequent application of the X-rays, it is necessary that not only the patient but also the physician, and all those persons who are entrusted with the use of the X-ray outfit, should be protected as far as possible against secondary



Figs. 1 and 2.—Two Examples of Siemens X-ray Outfits.

radiation of the tube. For this purpose, only that pencil of the X-rays should be allowed to come into contact with human beings which is required for application to a part of the body, that is to say, the application of the X-rays should be confined as far as possible to that part of the body only which requires treatment, and the physician as well as those persons entrusted with the use of the X-ray apparatus must be protected from all radiation. The patient himself is protected from accidental subjection to the rays by the use of diaphragms and protective devices. The most suitable means for protecting the physician and his assistants has been proved in practice to be a cabinet, the walls of which are lined with lead. This cabinet contains the controlling and regulating apparatus, and the physician is able to observe the tube and the patient through lead glass windows let into the sides.

An X-ray outfit of rather a different kind is shown in Fig. 2. It possesses the great advantage of being capable of being used direct on either a single-phase or three-phase supply. The demand for these new X-ray outfits was

determined by the necessity for generating absolutely unidirectional current for working the tubes and for generating large amounts of energy, in order to be able to make rapid and instantaneous exposures and good radiographs, and for obtaining an absolutely steady bright image on the screen. An X-ray outfit of this kind consists of two parts, a generating plant in a cabinet form and a trolley switchtable or a switchboard.

The generating plant consists of the following principal parts: (1) A high-tension transformer for 100,000 to 120,000 volts with a capacity of 4 k.v.a., that is to say, an output which is greater than that of an induction coil. These transformers possess a special advantage in that both high-tension terminals are well insulated from body and from earth. (2) A rectifying apparatus, which converts the high-tension alternating current supplied by the transformer into continuous current, which serves to work the tube. Messrs. Siemens' rectifiers are, it is claimed, specially characterised by the fact that no insulating material is used for the spindle, which is of steel running in ball bearings; that no rotary discs and insulating screens are employed, so that rotating arms of good insulating material well spaced apart move freely with the current-carrying conductors. (3) A driving motor, which in the case of single-phase or three-phase current is of the self-starting synchronous type, and in the case of continuous current is combined with an alternating-current generator. These parts are mounted in full view in the interior of a cabinet, which is made sound-proof. In order to render the apparatus suitable as well for radioscopy and radiotherapy, a high-tension switch is attached which reduces the number of current impulses through the tube by one-half. In the case of single-phase and three-phase outfits, a special device is provided by which it is possible to determine the polarity of the high-tension continuous current before switching in the tube.

Fig. 3 shows a type of universal electro-medical switch-table, for connecting to continuous-current mains and capable of being used in the application of galvanisation, faradisation and galvano-faradisation.

The current for galvanisation and light is generated separately by a small dynamo, and, therefore, there is no danger of the patient or the doctor receiving electric shocks in consequence of earth connections. The machines are made of such a size that even the largest cauteries and loops may be used. Special attention has been given to simplicity in regard to attendance and convenience. By the attachment of a flexible shaft, this apparatus can also be employed for vibratory massage and for drilling, milling and sawing as required for surgical operations.

A high-frequency apparatus is shown in Fig. 4. It is frequently employed for the medical application of high-frequency currents. It is known as the Oudin resonator, and the illustration shows a type which has been improved in construction and efficiency by Messrs. Siemens. The apparatus is connected to an induction coil, which charges the four Leyden jars under the table. These discharge themselves through a spark-gap fixed above them and through the windings on the lower part of the revolving solenoid, the effective number of which may be adjusted by a sliding contact. According to the adjustment of the number of windings, the resonance is more or less defined so that thereby a good regulation is obtained of the strength of the brush discharges, which are produced at the end of the electrode connected with the resonator. These apparatus are also specially suited for the production of auto-conduction of the human body by means of a large solenoid.

NOTES.

Provisional Order Applications.

THE Board of Trade have issued a revised code of rules with regard to applications for Provisional Orders under the Electric Lighting Acts, 1882 to 1909. The revision has been rendered necessary by the important and useful changes in the law relating to electricity supply introduced by the Electric Lighting Act of 1909. As many of our readers will be interested in the subject, we set out in another column extracts from the regulations, giving the principal modifications made and also the new rules of the Board in regard to applications for provisional orders for the constitution of joint (electricity) committees or joint boards, the supply of electricity in bulk, and the compulsory acquisition of land for generating stations. In regard to the purchase of land, these rules follow the procedure hitherto adopted in the case of bills and provide for due notice being given to the owners of the land to be taken, and also to owners and occupiers of land within 300 yards of the proposed generating station. Provision is also made for those cases where the Board have refused to grant a Provisional Order for the supply of electricity in bulk and it is intended to proceed by private bill. We are pleased to notice continued evidence in the rules of the Board's intention to insist that undertakers who have obtained orders should carry out their obligations within a reasonable time; and among other changes is the reduction of the fee from £50 to £35. The issue of the new rules marks a distinct step in advance in connection with electricity supply undertakings, and we believe that the cheapening and expansion of Provisional Order procedure will give an impetus to the development of electricity supply for power, lighting and industrial purposes in this country.

Glasgow New Telephone Exchange.

WHATEVER telephone troubles Glasgow has experienced in the past, they are, at all events, at an end now. Glasgow has always boasted of its municipal enterprise, and up to the time that the Corporation was seized with the idea of a municipal telephone system it could point to highly profitable undertakings under its control. Water, gas, electricity and tramways, when handled by the Corporation of Glasgow, were all so conspicuously successful that their management has been, and is, held up as a model for emulation by other municipal bodies. But municipal telephony in Glasgow was never able to compare satisfactorily, as a trading concern, with the other departments. There is a trite saying that "the man who never makes a mistake never makes anything," and the spirit of this must be also applicable to corporate bodies. The mistake of its municipal telephone system was, of course, shared by Glasgow with a number of other cities, but its experience with telephones in no way damped its ardour for municipal trading in those other departments mentioned for which it is evidently well suited. However, in the new Post Office Central Exchange the citizens of Glasgow and the people of the surrounding townships have facilities for telephone communication whose efficiency the now obsolete system of the Corporation could never have afforded them. The installation of the common battery system on so large a scale effects a considerable reduction in the list of call wire subscribers, and a complete change-over to common battery working is now merely a matter of time.

Digitized by Google

THE magnitude of the undertaking of the new exchange will be gathered from the detailed description of the equipment which appears elsewhere in this issue. One of the most satisfactory features of the installation is the employment, for the first time, of plant which has been manufactured wholly in this country. So much of our large telephone exchange work has been entrusted to American firms that they have come to be regarded somewhat as monopolists in this field. The General Post Office, in its new Glasgow telephone exchange, however, gives the clearest possible indication of its faith in home enterprise by placing the entire contract with a British firm, who have completed the work without hitch of any kind. This gratifying result is worthy of special comment, because it emphasises the presence in this country of a manufacturing organisation which can be relied upon to uphold the reputation of the old country in telephone matters. The work of the installation of large exchange equipments is now highly specialised, and it speaks volumes for the abilities of the contractors for the new Glasgow exchange that they have provided plant which is in the forefront of telephone developments. We may express the hope that this project will be but the first of a long series of successes for British-made telephone exchange apparatus.

Suburban Railways v. Trams.

THE chairmen of our great railway companies have long been wont, in their speeches at general meetings, to bewail the loss of suburban traffic and to ascribe this disastrous state of things to rate-aided tramway competition. It is obvious, however, that no amount of subsidising could have had the smallest effect if it had not been for rapid developments in electric traction; and these very developments are now providing the railways with a powerful weapon by the aid of which they can win back their lost ground. The effect of tramway competition seems now to have reached its maximum, and if the railway companies seriously wish to find a solution of the problem, they can do so by introducing electric traction and running a frequent service on their suburban lines. Suburban electric traction is no longer a matter for doubt, as may be gathered from the regular and efficient working of existing lines under the most arduous service conditions. It is, for instance, not surprising to find that by running a frequent service of electrically-worked trains at cheap fares the London, Brighton & South Coast Railway have succeeded in considerably increasing their suburban traffic and practically counteracting the effects of tramway competition.

WHILE the trains are not so frequent as the trams and the passenger cannot alight at his own door, yet the actual running is speedier and the net time occupied on the journey less. Moreover, as the permanent way is under the complete control of the railway company, while the roads are open to all and sundry, it is possible to arrange and adhere to some form of fixed time table, an advantage which cannot fail to be appreciated by the man whose minutes are valuable. That the advantages of such a suburban service are recognised by other railway companies is shown by certain proposals emanating from the Manchester district, where the traffic conditions are not unlike those which now prevail in London, particularly as regards the London County Council tramways. The suburban train service in Manchester is infrequent and is overshadowed by the Corporation's trams, but we feel sure that some arrangement of electrical working of the local trains like that lately introduced in London cannot fail to be successful. So vast an industrial area as that of Greater Manchester cannot now afford to be behind the metropolis in the matter of its suburban train service, and we hope to see the recent project, which is after all but the revival of a scheme mooted some years ago, come speedily to a practical head. Such a satisfactory development would give the lead to other similarly situated towns and a much needed stimulus to suburban electric traction throughout the country.

Electric Traction in Switzerland.—"The Times Engineering Supplement" states that the new electric railway from Martigny to Orsieres through the Val d'Entremont, Canton of Valais, is completed, and that the inauguration has been fixed for the 27th inst. The line, which is about 11¾ miles in length, will in time be prolonged to the foot of the Grand St. Bernard Pass, via Bourg, and from the climber's point of view will open up a new district—a second Zermatt—crowned by the Grand Combin, Grand St. Bernard, and on the western side by the Mont Blanc range. The line up Monte Mottarone, 4,890 ft. high, in the Canton of Ticino, will be opened, it is hoped, next month. The mountain overlooks Lake Maggiore, and is situated about equidistant from Baveno and Stresa. The total length of the line, which is mostly on the rack system, is about 6 miles, the gradients vary from 5 to 20 per cent., and the motive power is electricity, the installation giving 600 H.P. The cost is estimated at nearly £100,000, and the line will be one of the most picturesque in Switzerland.

Preservation of Wooden Poles.—At the last meeting of the National Electric Light Association a report was presented on this subject, and contained much valuable information and statistics. At present it is estimated that there are required for renewals between 500,000 and 600,000 poles per year, and that during the next 10 years this number will be increased to in the neighbourhood of 900,000 or 1,000,000. As a result of direct inquiry from a large number of transmission companies, the life of various timbers when used for transmission poles was given as follows: Cedar, 13½ years; chestnut, 12 years; cypress, 9 years; pine, 6½ years; and juniper, 8½ years. The committee of the Association recommends strongly that the companies should keep accurate and complete records of poles and cross-arms and collect authentic statistics and literature pertaining to wood preservation. It also recommends the seasoning, and in most cases preservative treatment, of wood. It is claimed that a well-seasoned untreated pole will last at least 30 per cent. longer than an untreated green pole. Directions are given for seasoning, and illustrations show clearly how the poles should be piled. The theory and various methods of wood preservation are also described in considerable detail. No particular process is recommended for all conditions, although experience seems to indicate that coal-tar creosote gives the best results as a preservative, and that the high-pressure process of applying creosote is more flexible.

Personal.—On the occasion of the 80th birthday of the Emperor and King, Francis Joseph I. of Austria and Hungary, a special honour was conferred upon Mr. Etienne de Fodor, general manager of the Budapest General Electric Co. The official gazette of Hungary brought the news that the King had with a renewed document confirmed and certified the ancient line of nobility from which Mr. de Fodor's family sprang, and before whose name the predicate "Varkony" is attached. These original papers and family documents were lost during the past wars and political disturbances, and on the 18th inst., in recognition of the scientific services which Mr. de Fodor has rendered, the King has been pleased to reconfirm by Royal Decree his family's pedigree.

Comparison of Arc Lamps.—In a Paper read before the National Electric Light Association and entitled "Magnetite and Flaming Arc Lamps versus Open and Enclosed Carbon Arc Lamps for Street Illumination," the author, Mr. W. d'A. Ryan, compared the 9·6-ampere open arc, the 6·6-ampere enclosed arc, the 4-ampere luminous arc, the 6·6-ampere luminous arc and the 6·6-ampere flaming-arc lamp with vertical electrodes. In the order here indicated, these lamps gave 0·8, 0·9, 1·1, 1·4, and 3·6 mean spherical candle-power per watt, or 1·2, 1·7, 1·7, 2·6 and 5·8 mean lower hemispherical candle-power per watt. The distances from the lamps at which equal illumination would be obtained are 250 ft., 285 ft., 315 ft., 475 ft. and 637 ft. Each of the above lamps was assumed to be operated at a normal E.M.F. of from 70 volts to 80 volts, direct current. In the most highly efficient lamp, use is made of specially treated carbon electrodes, which cost from £4 to £6 per year more than do the electrodes for the 6·6-ampere luminous-arc lamp.

An Electric Light Company and the Telephone.—From a recent issue of the "Electrical World" we gather that in some small installations in the United States there is distinctly friendly working between the electric light and telephone undertakings. There appears to be a small independent telephone exchange near Columbus, Ohio, which has had some trouble in the operation of its lines at night, owing to the proximity of the high-potential alternating-current circuits of the electric light company. It is said that, owing to induction, it is almost impossible to hear over some of the telephone lines because of the noise, but in spite of this the kindness of the electric company enables the telephone people to do some business. When a night call comes in for a physician, or any call which is believed by the operator to be urgent, she telephones the lighting company to shut off the supply of electricity in the village, while the conversation is being held. With this request the electric light company obligingly complies, and the conversation is uninterrupted. Evidently the users of light in that neighbourhood are both easily satisfied and very kindly-disposed folk.

Performance of an Electric Shunting Locomotive.—According to the "Railway and Engineering Review," the Hoboken R.R., Warehouse & Steamship Co. have had in operation since May, 1906, a 60-ton electric shunting locomotive which, it is stated, has given remarkably continuous and economical performance under varying and severe load conditions. Since the electric locomotive was placed in operation four years ago there has not been replaced a single contact on the switch group or a contact on the master switches or reverser, while on the control apparatus only two tips on the live switch have been replaced. The brushes that are in the motors at the present time have been operating 14 months, and it is believed that they will operate at least six months longer without replacement. No trouble has been experienced with broken brushes. Except that there has been replaced one pinion which was broken when a lock washer dropped into the gears, no repairs on the motor have been necessary. The cost of inspection and cleaning has been practically nil. Every Saturday morning the man operating the locomotive makes an inspection of the equipment. With compressed air he blows out the motor and the various parts of the control apparatus, and cleans any part that may need it with a piece of cloth. This work is not charged to maintenance, as the operator in doing it is simply filling in his time. No extra time is needed for maintenance or inspection. The locomotive has a running and a starting drawbar pull of 14,500 lb. and 30,000 lb. respectively, and has a normal speed of 12 miles an hour. It is fitted with four 100 H.P. slow-speed motors, a hand operated unit switch control, and air brakes and compressor.

Wireless Equipment of Lightships.—According to the "Electrical Review and Western Electrician," the United States Lighthouse Board recently furnished a statement of the amount of wireless apparatus that would be required for installation upon vessels belonging to the lighthouse establishment. Only such vessels as go out of sight of land are to be so equipped. There are at present about 20 lighthouse tenders which go out of sight of land and upon which a wireless apparatus could be installed. Besides this number there are 10 other lighthouse tenders which may possibly go out of sight of land occasionally. At the present time none of these tenders is equipped with wireless apparatus, but steps are now being taken to instal a plant of this character upon the tender "Kukui," which does service in Hawaiian waters. Wireless equipment is already in use on four lightships. Six lightships which are stationed 13 miles or more from the nearest land are not provided with wireless equipment and such apparatus might be installed upon these vessels. It is estimated that the cost of installing wireless telegraph apparatus on vessels of the lighthouse establishment would aggregate £700 for each vessel to be so equipped.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. D. Shirt contributes an article on "An Overlap Loop Test."

We continue our description of the new Post Office telephone exchange at Glasgow.

Mr. W. Winsborough gives particulars of the electrical installation at the Rose Bridge and Douglas Bank collieries, Wigan.

We analyse the electricity supply accounts of the Burton-upon-Trent Corporation.

In our correspondence columns Mr. R. Beattie replies to the criticism by Prof. D. Robertson of his article on the "Quadrant Electrometer."

Newcastle-on-Tyne Tramways Committee are considering the advisability of adopting the rail-less trolley system of traction.

The Lancashire & Yorkshire Railway Co. propose to extend their electrically operated train service so as to include the belt route between Liverpool, Ormskirk and Southport.

The Board of Trade have issued a revised code of rules with regard to applications for electricity supply provisional orders.

Loans for Electricity Undertakings.—The L.G. Board have sanctioned a loan of £40,000 for extensions of the Manchester electricity supply undertaking, without holding a local inquiry.

West Ham Corporation have also received permission to borrow sums amounting to £118,525 for their electricity department.

Inquiries have also been held at Peterborough and Bury St. Edmunds into applications for sanction to loans.

Dartford Council have applied for sanction to a loan of £11,000 for electricity supply extensions.

Directors' Report.—The report of the directors of the Yorkshire Electric Power Co. states that the company is making steady progress, and the receipts for the sale of current show a considerable advance over those of the corresponding half-year of 1909.

ARRANGEMENTS FOR THE WEEK

BRITISH ASSOCIATION.

WEDNESDAY, August 31st.

Meeting at Sheffield. Presidential Address, in the Victoria Hall, by the Rev. Prof. T. G. Bonney, Sc.D., F.R.S.

THURSDAY, September 1st.

Addresses by the Presidents of the various Sections. To Section A (Mathematical and Physical Sciences), by Prof. E. W. Hobson, F.R.S. To Section G (Engineering) by Prof. W. E. Dalby, M.A.

[A list of the various Papers to be read during the meeting, which lasts until Tuesday, Sept. 6th, was given in our issue of Aug. 5, p. 676. The actual days on which these Papers will be read will only be announced at the meeting.]

BURTON-UPON-TRENT ELECTRICITY SUPPLY ACCOUNTS.

The progress made by the Burton-upon-Trent electricity undertaking is always watched with interest by electrical engineers. The annual report of Mr. P. J. Pringle, borough electrical engineer and tramways manager to the Corporation, for the year ended March 31st last, states that the surplus on the present occasion is the largest so far recorded by the electricity undertaking, viz., £1,474. This result is the more satisfactory in that although the output of electrical energy is practically the same as that recorded a year ago, the revenue has decreased, whilst the average price per unit sold is slightly less. It is evident, therefore, that considerable economies have been introduced in the costs of generation. We referred to this point at some length in our issue of May 13th, and further mention of it is made below.

Considering in detail the output of energy, the revenue obtained from private lighting shows a reduction of £206, as compared with last year's figure, due to the further introduction of metal filament lamps and to the effects of bad trade. It is actually less than the figure recorded seven years ago. On the other hand, an increase of £25 is recorded in the revenue obtained from the sale of heating and power units, and an increase of £38 due to an increased output for traction. The net result is a decrease of £149. The number of units sold for private lighting was 300,774, as against 317,129 in 1908-9; for motors 544,484, as against 533,390; and for heating, &c., 16,120, as against 15,159, whilst 1,190 units were sold for public lighting. The Corporation electric tramways required 617,199 units, an increase of 7,310 over the previous year's demand, whilst the Burton & Ashby Light Railways purchased 49,833 units, as against 51,084 units in 1908-9. The total sales, therefore, amounted to 1,529,600 units, an increase of only 1,759 units compared with the output for the previous year.

During the 12 months 53 new lighting consumers were connected to the mains, bringing the total number of lighting consumers to 605, whilst the number of power consumers increased during the same period from 67 to 76. It is interesting to notice that the increase in lamp connections is the lowest recorded for many years. This result is very different from the experience elsewhere, as the advent of the metal filament lamp has generally caused an acceleration in the rate at which lamps are connected to the mains. The unfortunate state of trade in Burton, however, is stated to be accountable for this slow progress.

The total horse-power of motors connected to the mains is now 933, the connections during the past year accounting for 156 H.P. of this total. As applications for 10 motors, representing 118 H.P., were in hand in April of the present year, it is evident that considerable expansion of output is likely to be recorded next year.

In view of the small change in the total output of units, it is not surprising that on the present occasion the maximum demand for lighting and power is almost identical with that recorded a year ago, viz., 500 kw. in 1909-10 and 504 kw. in 1908-9, the maximum traction demand in each year being 375 kw. The corresponding load factors naturally show little change, being 19·69 per cent. and 20·3 per cent. for lighting and power and traction respectively. The capacity of the generating plant remains at 1,710 kw.

In regard to the revenue, the average price obtained for lighting was 4·86d., the figure for the previous year being 4·61d.; whilst for power and heating units the average price obtained was 0·97d., as against 0·98d. last year. For the whole supply the average price was 1·875d.

One of the most interesting features of the Burton electricity undertaking is the restricted-hour power supply. On March 31st last, of a total of 933 H.P. in motors, no less than 744 H.P., or 80 per cent., was supplied on the restricted-hour system. During the 12 months the number of units sold on this system was 430,246, 94,736 of these units being charged at 1d., 76,412 at ⅞d., 58,796 at ¾d. and 200,302 at ⅝d., the average price, therefore, being 0·855d. As the expense of generating restricted-hour units is only about 35 per cent. of the revenue obtained, it is evident that the load must prove very profitable to the supply undertaking.

From the analysis of the expenditure below it will be seen that the total costs have been reduced during the year from 1·03d. to 0·92d., this excellent result being accounted for by a reduction in the fuel item from 0·38d. to 0·28d.; and the costs are now for the first time below 1d. per unit. The important economies introduced in the boiler house, together with the lower price of coal, have resulted in a reduction of £644 or 27·6 per cent. in the total cost of fuel, notwithstanding that the output was slightly higher during the year 1909-10. Of this reduction £418 is attributable to greater economy in working, the remaining £226 being accounted for by the lower prices of coal prevailing throughout the year. Taking into consideration the size of the undertaking, the figure of 0·28d. per unit for fuel reflects the greatest credit on Mr. Pringle and his staff.

We give below an analysis of the expenditure during the year ended March 31, 1910, together with the cost per unit sold for each item, the latter figure for the previous year being also included to facilitate comparison:—

		Cost per unit sold. 1909-10.	1908-9.
Generating Costs.			
Fuel	£1,811	0·28d.	0·38d.
Oil, waste, stores, &c.	362	0·06d.	0·06d.
Salaries and wages at station	1,236	0·19d.	0·19d.
Repairs and maintenance	812	0·13d.	0·14d.
Total Generating Costs	£4,221	0·66d.	0·77d.
Distribution Costs.			
Wages	£34	0·01d.	0·01d.
Repairs and maintenance of meters, motors, &c.	284	0·04d.	0·03d.
Total Distribution Costs	£318	0·05d.	0·04d.
Management Costs.			
Salaries	452	0·07d.	0·07d.
Printing, stationery, &c.	26	0·00d.	0·00d.
Insurance	36	0·01d.	0·01d.
Miscellaneous	117	0·02d.	0·02d.
Total Management Costs	£631	0·10d.	0·10d
Rates and taxes	£683	0·11d.	0·12d.
TOTAL COSTS (*ex.* capital charges)	£5,853	0·92d.	1·03d.
Capital Charges.			
Interest	£2,056	0·32d.	0·34d.
Sinking fund	3,091	0·49d.	0·45d.
Total Capital Charges	£5,147	0·81d.	0·79d.
TOTAL COSTS (*inc.* capital charges)	£11,000	1·73d.	1·82d.
TOTAL REVENUE (from all sources)	£12,474	1·96d.	1·96d.
Surplus	£1,474	0·23d.	0·14d.

This surplus has been allocated as follows:—To capital cost of meters, £166; to stock motors, £129; to capital cost of instruments at power station, £24; carried to renewals fund, £1,155. A further sum of £191 is being transferred to the renewals fund on account of a rebate of income tax for the years 1907-8 and 1908-9. This fund now stands at £4,441, or 5·3 per cent. of the total capital expenditure, which latter amounted on March 31st last to £83,395, an increase of £816 during the past year.

THE ELECTRICAL PROPULSION OF FRENCH SUBMARINES.*

BY J. BREGUET.

At a time when the application of electricity to marine propulsion is so widely under discussion, the following notes on the electrical equipment of the latest French submarines will be of interest to all engineers.

The "Mariotte," "Archimède" and "Amiral Bourgois" of the French 1906 programme have recently completed their tests. These vessels are of about 800 tons displacement, a total horse-power of over 2,000; they have a large radius of action, are habitable, and, in fact, war vessels for offensive operations.

Each vessel has two screws and on each shaft are mounted a thermal prime mover (gas or steam engine) and an electric motor.

* Abstract of an article in "La Lumière Electrique."

Digitized by Google

During surface cruising the former drives the vessel and also recharges the accumulator batteries, the motors being meanwhile used as dynamos. When submerged, propulsion is wholly electrical, the maximum speed obtained being 10 knots, the maximum surface speed being about 14 knots. Each motor has practically continuous speed variation from rest to full speed, and, each shaft being controlled quite independently of the other, very quick manœuvring is possible. All manœuvring (such as coming alongside, entering and leaving port, reverse running, picking up course, &c.) is best done, even at the surface, by aid of the electric motors; this course is essential if gas engines be the prime mover and is highly admirable even with steam engines.

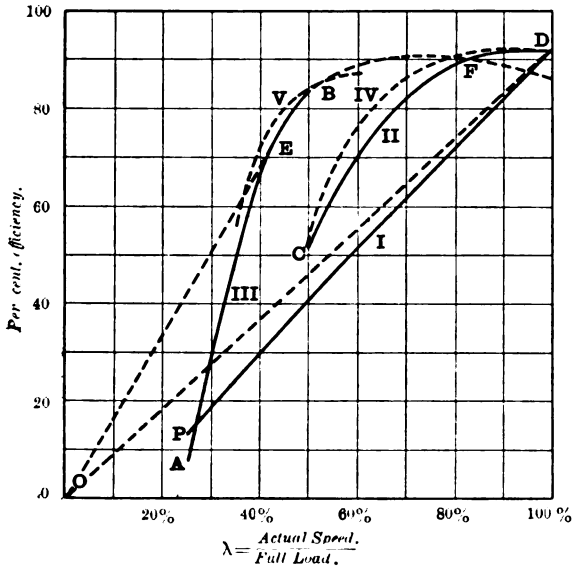
The motors having to fulfil stringent requirements, as regards insulation, heavy and variable duty and use as generators, must be robust and specially designed. A high efficiency is of the greatest importance since, on the efficiency, the radius of action between charging directly depends. Direct-current motors are invariably employed.

Methods of Speed Variation.—The methods used are

(*a*) By use of series armature resistance, reducing the effective applied voltage.

(*b*) By varying the field strength the terminal voltage being constant.

In case (*a*) commutation is good, the field strength being constant, while in case (*b*) special commutating arrangements are necessary since at low fluxes the armature reaction is proportionately high. Compensating windings and auxiliary poles have so completely over-



Efficiency Curves.

come the latter objection that the only practical disadvantages of method (*b*) are the slightly lower efficiency, the higher price and the greater complication. Weight and space considerations make the net balance incline to (*a*). The dimensions and weight of the motor required are, then, those of the standard motor giving P horse-power at N knots and U volts terminal pressure; on reducing U by the addition of armature resistance R_A the speed falls in proportion to the net terminal voltage E (φ being constant); the couple decreases in proportion to (speed)^2 hence the armature current remains constant.

Employing method (*b*), the weight and volume of the equipment depend directly on the minimum speed required with maximum field but no armature resistance. Let this speed be $N_3 = \frac{N}{3}$; then, by supplying the motor with full voltage at full flux, it would, at speed N, give three times the desired output. Such a motor would be unnecessarily costly, bulky and heavy and for this reason it is usual to compromise with a minimum speed of $N_2 = \frac{N}{2}$ at full flux.

Efficiency Considerations as affecting the choice of a speed regulating system:—

Case (*a*). Let N be the normal (maximum) speed,
I be the armature current (at speed N),
U be the voltage of supply,
E be the armature terminal P.D.

Then (U—E) = voltage absorbed by rheostat R_A,
and U = E at speed N.

Further let U × I = P watts,
P_e = Power dissipated in shunt field,
P_i = C^2R losses in armature, brushes, connections
P_p = Iron losses (eddy + hysteresis) + friction losses (bearings, brushes and windage).

Then P_e is constant: $P_i \propto I^2$, *i.e.*, $\propto$ (speed)^4 and the hysteresis losses $\propto$ speed; the eddy losses $\propto$ (speed)^2 and the windage losses $\propto$ (speed)^3 so that it is found that $P_p \propto$ (speed)$^{\frac{3}{2}}$.

If λ be the ratio of the actual speed N′ to the normal speed N and P'_e, P'_i, P'_p the corresponding losses, then

$$P'_e = P_e : P'_i = P_i\lambda^4 : P'_p = P_p\lambda^{\frac{3}{2}} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The armature terminal volts at N′ = E′ = Eλ, so that the rheostat loss $P'_r = (U - E\lambda)I'$ and E = U and $I' = I\lambda^2 \therefore P'_r = (1-\lambda)UI\lambda^2$, hence

$$P'_r = P(1-\lambda)\lambda^2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

In machines of about 200—600 B.H.P., 300 revs. per min., such as are here concerned, we have, at full load,

$$\left.\begin{aligned} P_e &= P \times 0{\cdot}015 \\ P_i &= P \times 0{\cdot}03 \\ P_p &= P \times 0{\cdot}04 \end{aligned}\right\} \text{(approx.)}. \quad . \quad . \quad . \quad (3)$$

Now the efficiency $\eta = \dfrac{P - (P_i + P_r + P_p)}{P + P_e}$, which, substituting from equations (1), (2) and (3) gives

$$\eta = \frac{\lambda^2 - (0{\cdot}03\lambda^4 + 0{\cdot}04\lambda^{1{\cdot}5} + (1-\lambda)\lambda^2)}{\lambda^2 + 0{\cdot}015},$$

i.e.,

$$\eta = \frac{\lambda^3 - (0{\cdot}03\lambda^4 + 0{\cdot}04\lambda^{1{\cdot}5})}{\lambda^2 + 0{\cdot}015}, \quad . \quad . \quad . \quad . \quad . \quad (4)$$

whence follow the results in Table I.

Table I.

λ	η	
1·00	0.916	Curve I. (*see* figure).
0·75	0·669	
0·50	0·412	
0·25	0·130	

For very small values of λ, η is negative, the equation (4) being only approximately true; over the whole practical range of λ the equation is sufficiently accurate. Owing to the variations in the losses, the current I follows a complex law of variation with λ; equation (4) is sufficiently accurate until the losses become comparable with the useful power; the true efficiency is actually somewhat greater than is given by Table I.

The shape of the efficiency curve (I. in figure) is significant; it is approximately linear and at half speed only 40 per cent. total input is available at the motor shaft, the bulk of the remainder is dissipated by R_A. Owing to this inefficiency the range of action is small, or for a given range the battery equipment is heavy; hence method (*a*) of speed regulation is now only of secondary importance.

Method (*b*).—Constant voltage; variable field. Let the minimum permissible speed at maximum field be N/2.

Let P = volt amperes absorbed by the armature,
P_p = Σ mechanical and iron losses,
P_i = C^2R losses in armature, series field, auxiliary poles and compensating windings,
P_e = C^2R losses in shunt field.

Then since I $\propto$ (speed)^1 $\therefore$ $P_i \propto$ (speed)^6,

i.e.,

$$P'_i = P_i \times \lambda^6. \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

With decreasing speed the mechanical losses $\propto$ (speed)^1 ..... the magnetic losses increase on account of the stronger field but decrease on account of the lower frequency, so that the net variations of P_p over the present limits of field and speed are small. The losses are slightly greater at the minimum than at the maximum speed, and the loss curve has a minimum at a speed equidistant from the two extremes; for the present purposes, however,

$$P'_p = P_p. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The law of variation of P_e depends on the load characteristic of the machines; between the present limits of induction the characteristic may be taken as the arc of a hyperbola. The maximum flux

Table II.

λ	η	
1·00	0·916	Curve 2 (*see* figure).
0·75	0·860	
0·50	0·515	

Digitized by Google

being at speed N/2, we may assume the asymptotes of the hyperbola to correspond to abscissa N/3.

Then $$P'_e = P_e \times \frac{2}{3\lambda - 1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

and $$\left.\begin{aligned} P_i &= 0{\cdot}035P \\ P_p &= 0{\cdot}040P \\ P_e &= 0{\cdot}010P \end{aligned}\right\} \text{(approx.)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

$$\therefore \eta\left(=\frac{P - P(P_i + P_p)}{P + P_e}\right) = \frac{\lambda^3 - (0{\cdot}035\lambda^6 + 0{\cdot}04)}{\lambda^3 + \left(0{\cdot}01 \times \frac{2}{3\lambda - 1}\right)} \quad . \quad . \quad (9)$$

which gives the results shown in Table II.

The speed N/2 ($\lambda = 0{\cdot}5$) being the minimum obtainable by field regulation, lower values are secured by armature rheostats (much smaller than in case (*a*)). Henceforth the efficiency closely follows the line joining point C (0·50, 0·515) to the origin (0, 0). (*See* case (*a*)).

A comparison of curves I. and II. shows that method (*b*) secures much the better efficiencies particularly at high speeds; at half speed the advantage is very slight. Here the gain, possible by method (*b*), only that indicated by the relative position of curves I. and II.; the great increase in weight, cost and complexity entailed by (*b*) would hardly be justified. Though method (*b*) has been used in its simple form, it is dealt with here rather as an introduction to the most recent methods of speed control.

At point C the terminal voltage is E, and, N′ being = N/2, $\phi' = 2\phi$; if now E be reduced to E/2 only the original field ϕ would be required to preserve half speed. The speed being constant and the induction B being halved, the iron losses would fall in proportion to a power of B somewhere between 1·6 (hysteresis) and 2·0 (eddy), *i.e.*, P_p, which was originally 0·04P (*see* equation (8)) would then lie between $\frac{0{\cdot}04P}{4}$ and $\frac{0{\cdot}04P}{3}$, *i.e.*, would = 0·0115P (say) . (10).

The output being constant and V halved, C must be doubled . ·. P_i is quadrupled, *i.e.*, $$P_i = 0{\cdot}140P\lambda^6. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

The field induction has resumed its original full load full speed value, but $\lambda = 0{\cdot}5$, hence the new hyperbola asymptote is $\lambda = \frac{1}{2 \times 3} = \frac{1}{6}$

and $P'_e = P_e \times \frac{2}{6\lambda - 1}$ and $P_e = P \times 0{\cdot}01$

$$\therefore P'_e = \frac{0{\cdot}02}{6\lambda - 1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

so that $$\eta = \frac{\lambda^3 - (0{\cdot}14\lambda^6 + 0{\cdot}115)}{\lambda^3 + \frac{0{\cdot}02}{6\lambda - 1}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

giving

Table III.

λ	η	
0·500	0·830	Curve 3 (*see* figure).
0·375	0·585	
0 250	0·575	

Note that curves II., III. lie somewhat below the actual test curves IV., V., so that equations (4), (9) and (13) can be relied upon as giving the minimum efficiencies likely to be obtained in practice.

Curves 2 and 3 simply illustrate, in a new connection, the well known advantages obtainable by series parallel control; in this case a submarine can run at half speed, a convenient and usual cruising speed, at practically as high an efficiency as at full speed. The simplest method of obtaining the requisite 2:1 pressure step at half speed would be to place two motors on each shaft, coupling the machines in series or parallel according as full or half speed be desired. The objection to having two motors per shaft when one would suffice is sufficiently serious in submarine work, but the vital disadvantage of the suggested simple series-parallel arrangement is, that if the slightest inequality in the field-strengths of the two machines be introduced during their regulation, one armature at once takes the whole load, the second acting as a generator feeding the first; heavy circulating currents flow, the armatures are overheated, if no worse, and the circuit breakers continually open.

The load distribution between the two rotors, mechanically compelled to the same speed, depends entirely on the relative fluxes in which they run and is so unstable that series-parallel operation of variable shunt field machines, on the above system, is impracticable.

Actual arrangement on board the "Mariotte."—Instead of connecting two armatures in series or parallel, the Breguet firm (responsible for the electrical equipment of the "Mariotte" and her sister vessels) have adopted the use of two half batteries connected in series or parallel at will. The efficiency as a function of the speed varies as follows: From full to ¾ speed the efficiency falls slowly from 92 to 85 per cent., from ¾ to ½ the efficiency falls rapidly, finally (at $\lambda = 0{\cdot}5$) being only 50 per cent. The two halves of the battery, hitherto in series, are now parallelled. The efficiency rises abruptly to over 80 per cent. in consequence of the halved voltage; between ½ and ¾ speed the efficiency remains good and then falls very rapidly to join, at ¼-speed, the efficiency curve obtained by the first method (series batteries). For speeds below $\lambda = 0{\cdot}25$ a series armature resistance is employed for speed regulation.

The efficiency-speed curve when running with constant field and variable pressure is practically a straight line through 0 (*see* notes on method (*a*)), hence it is economical to keep the field fixed and operate by series R_A at speeds below that at which the tangent to the field regulated efficiency curve passes through 0 (*see* point E in figure). Thus, contrary to what one might expect *a priori*, it is advantageous to regulate at low speeds by armature resistance, keeping a medium field strength, rather than by the use of abnormally strong excitation and constant supply pressure.

The dotted portion of curve III. of diagram has been supplied by calculated extrapolation; it shows the efficiency with the batteries *in parallel* to lie between 85 and 90 per cent. over the range $\lambda = 0{\cdot}5$, $\lambda = 1{\cdot}0$. The point of intersection F of II. and III., at about 0·85 × full speed, is clearly the theoretical point at which the conversion from series to parallel connection should occur. The armature current is then $I' = I \times (0{\cdot}85)^3 \times 2 = 1{\cdot}225$ I.

It is not advisable to work at so high a point of conversion as F because the field is then unduly weak as compared with the increased armature reaction; further, the armature heating is then excessive. By converting at $\lambda = 0{\cdot}75$, however, $I' = I \times (0{\cdot}75)^3 \times 2 = 0{\cdot}841$, *i.e.*, the current is less than its full load full speed value. A valuable gain in efficiency at speeds between $\lambda = 0{\cdot}5$ and $\lambda = 0{\cdot}75$ is thus obtained by the use of suitable R_A and field regulation, conversion from series to parallel connections being at ¾ speed.

The provision of sufficient field regulation to vary the speed from $\lambda = 1{\cdot}0$ to 0·75 enables the speed $\lambda = 0{\cdot}375$ to be reached simply by converting the battery sections from series to parallel connections; the tendency is, however, to provide as small an armature resistance as possible with a minimum number of stops, as low a speed (say, $\lambda = 0{\cdot}25$) as possible being obtained solely by field regulation. This course is dictated by operating conditions and not by efficiency considerations. . . . . (α)

At low speeds the efficiency is less dependent on the latter; the total power concerned is small and the useful energy may become less than the losses.

Actual arrangement on board the "Archimede."—Series-parallel armatures are adhered to on this vessel, while, to avoid the difficulties of instability of load, both windings are on one core, and hence, of necessity, always in equal fields. Two commutators are required and only one supply battery. Inherently the solution is no different from that employed on the "Mariotte," but the practical advantages are as follows:—

1. The current per commutator (in parallel) is only one-half its value in the "Mariotte" under the same conditions; commutator design and operation is thus facilitated.

2. Series-parallel connections between the switchgear and motors are very short, the boards being as near the motors as possible, whereas series-parallel leads from switchboards to accumulators are much longer, the latter being in a separate compartment, usually at the other end of the vessel.

3. Advantages in accumulator charging as below.

Charging Accumulators.—The electric motors which drive the submerged submarine act as charging dynamos during surface running; the prime movers of the vessel must be able to drive the latter at the desired maximum speed on the surface, meanwhile leaving a sufficient balance of power to recharge the battery within reasonable time.

Let the maximum surface and submerged speeds be N_t, N_e. The torque of a thermal engine being roughly constant at all speeds the output $P_t \propto$ speed,

so that $$P_t = P_{t\max.} \times \lambda, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

The power absorbed by the screw $\propto \lambda^3$

i.e., $$P_h = P_{t\max.} \times \lambda^3, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

hence the available surplus power on the shaft

$$= P_d = P_{t\max.}(\lambda - \lambda^3), \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

which is a maximum when $\lambda = \sqrt{\frac{1}{3}} = 0{\cdot}576$, so that under the most favourable conditions the excess power available for cell charging is

$$P_d = 0{\cdot}384 \times P_{t\max.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (17)$$

In the present instances the surface speed is about 40 per cent. > submerged speed, this necessitating a horse-power of prime mover = about 3 × horse-power electric motors.

Digitized by Google

Then P_d is a maximum for a speed

$$= 0{\cdot}576N_d = 0{\cdot}576 \times (1{\cdot}4N_e) = 0{\cdot}8N_e \quad . \quad . \quad . \quad (18)$$

It is best to recharge all the cells in series, this ensuring the same current through all; the motors running as generators must be able to attain an E.M.F., say, 40 per cent. above the normal discharge voltage of the cells. The motor field should not be above 80 per cent. its full strength during charging, the efficiency having been shown to be poor at high excitation, besides which, the field coils become very hot if run fully excited for such long periods.

The normal maximum voltage E_m is obtained from the motors at a speed of $0{\cdot}5N_e$ with full excitation; hence, to secure ($E_m + 40$ per cent.) volts with a flux of only $0{\cdot}8\ \phi_{max.}$ requires a speed

$$N_e = \frac{0{\cdot}5 \times 1{\cdot}4}{0{\cdot}8} N_e = 0{\cdot}875N_e \quad . \quad . \quad . \quad . \quad . \quad (19)$$

clearly a fortunate coincidence with the requirements of equation (18).

Thus between $0{\cdot}8$ and $0{\cdot}9 \times N_e$, *i.e.*, at about $0{\cdot}6 \times$ the maximum surface speed, a good cruising speed, charging conditions are at their best.

If P_e be the maximum output of the motors then, since

$$P_{max.} = 3P_e \ : \ P_d = 3P_e \times 0{\cdot}384 \ (see\ (17)) = 1{\cdot}15P_e, \quad . \quad . \quad (20)$$

i.e., the charging load is rather above the maximum output of the motors on minimum flux, but quite within their capabilities at $0{\cdot}8\phi_{max.}$ excitation.

Time of Charging.—The batteries maintain an output of P_e kilowatt at a speed of $0{\cdot}715N_e$ during H hours;

$$\text{hence the charging period} = H' \text{ hours} = \frac{H}{0{\cdot}5 \times 1{\cdot}15} = 1{\cdot}75H \quad . \quad . \quad (21)$$

(assuming an overall efficiency for batteries, leads and generators of 50 per cent.). The charging period is 75 per cent. longer than the discharge period, but whereas discharge occurs with a vessel speed of $0{\cdot}715N_e$, charging takes place at $0{\cdot}6N_e$ (20 per cent. slower).

A double commutator motor allows of recharging at a lower speed of motors and vessel, for, by connecting the commutators in series, the requisite E.M.F. can be obtained at ½ speed (with maximum flux),

$$i.e., \ N''_e = 0{\cdot}25 \times \frac{1{\cdot}4}{0{\cdot}8} N_e = 0{\cdot}4N \ (see\ (18), (19)) \quad . \quad . \quad (22)$$

This ability to obtain a given charging voltage at half the speed otherwise necessary is a very valuable advantage in the present case.

Practical Difficulties; Future Developments.—The above considerations show some of the conditions and difficulties to be met with in the electrical equipment of submarines. Practical difficulties far greater than would appear from the above have to be overcome at every stage in the vessel's building and equipment; among the chief of these are:—

1. The very limited space available for motors.
2. The poor ventilation and cooling obtainable.
3. The humidity of the atmosphere and consequent insulation difficulties.
4. The complexity of the control gear, further hampered by space restrictions and the essential need for reliable and rapid operation. (The Védovelli Priestley controllers are used on the "Mariotte" and "Archimede.")

Future developments in the electrical equipment of submarines will probably be on the following lines:—

1. Higher voltages, probably 480 volts, will be employed in the main motor circuits only. This will lead to the saving of considerable space and copper, both in the motor rotor and in the armature rheostat, battery, leads, &c.

The difficulty of providing adequate insulation will be reduced by confining the high-tension circuits to the main motors. All lighting, contactor solenoids, field bobbins, starting resistances and, above all, the connections and contacts of the controllers would still be low-tension (120 v. or 240 v. = ¼ or ½ main battery respectively) and of normal insulation. The high-tension battery leads could be easily insulated, but the maintenance of the motor insulation, particularly in the armature, will involve

2. The use of completely enclosed motors in place of the present open type. Inspection doors for brush examination will be required as usual. Total enclosure will, in turn, involve:—

3. The use of water cooling, such as is already employed in high-tension transformers. Circulation of the water will be maintained naturally or by circulating pumps.

4. All main switches will be of the oil-break type; very strong and easily accessible. Their number will be reduced to a minimum by the reduction of the armature resistance (*see* note (α) above).

Minor contacts, then as now, will offer no difficulties.

Such are the tendencies in French submarine construction; the developments foreshadowed will be largely realised in the new vessels of over 1,000 tons displacement already under design.

DRY CELL TESTS.*

BY F. H. LOVERIDGE.

Summary.—The author gives some useful data regarding the fall of E.M.F. and increase in internal resistance of dry cells under ordinary working conditions. His figures embrace those obtained from tests carried out when cells were allowed to send currents for lengthy and continuous periods, as well as others obtained by causing the cells to send intermittent currents such as are required for ignition work.

If we are to judge by numerous inquiries from users of "dry cells" as to the electrical qualities which such cells possess, the conclusion is reached that ideas along this line are very indefinite.

It would seem to be a very desirable thing to have dry cells rated on an ampere-hour or watt-hour basis under some definite condition of energy discharge, but such a thing is practically unknown at the present time. The rating we now have is that of dimensions of the cell and its current. The first might be accepted as reasonable, but the second is misleading. Amperage ratings are high and apparently based on the instantaneous current a cell gives when short-circuited through a low resistance ammeter; such readings are of practical value in discovering defects, but so far as determining an energy output is concerned, they are of little value because the sustained current a cell can give has very remote relation to the short-circuit current. The voltage reading is also useful in discovering defects, but inasmuch as the cell may give out a very considerable part of its energy and cause only a small drop in this value it follows that such readings are not of much importance.

The "shelf test," or, in other words, the test made after a cell has remained for a certain time in storage, is one that serves a useful purpose, for the reason that it is desirable to know the change that takes place during such period. Very few cells go into service immediately after they are made, and during the delay more or less deterioration takes place. There is, however, the difficulty that if the test comprises readings of current with a low resistance ammeter, a decrease of 50 per cent. in its value would indicate only an insignificant increase in internal resistance, which would be unimportant with ordinary current drains. If current readings are taken with a resistance inserted in series, then the variation showing the change in internal resistance is correspondingly reduced. Where it is desired to take the current and voltage of a cell, it should be done by means of instruments that do not absorb a large part of the energy in themselves. Hence a high resistance voltmeter and a low resistance ammeter should be used—a minimum of 150 ohms for the voltmeter and a maximum of 0·01 ohm for the ammeter are found to be satisfactory values. Taking everything into consideration it appears that the best shelf test is one that compares the actual performance under working conditions of the cell after a certain length of time on shelf, with that of a new cell. In this way results are obtained that involve no factors of uncertainty. There is involved in this the using up of cells to find out what they will do on life test. Such procedure, however, seems necessary, since other methods involving tests not absorbing energy are not dependable and sample cells used up on life tests do not represent very great expense.

Deterioration is shown by an increase of internal resistance, inasmuch as voltage readings decrease very slightly on the shelf. It is impossible to give any exact data as to the increase of internal resistance on the shelf, because there is such a wide variation even in cells of the same make, but, roughly, it might be said that a reduction in the short-circuit current of 50 per cent. would be a fair average in one year at ordinary temperatures. The question of change in internal resistance from change in temperature is sometimes brought up. One test in which a decrease from 100°F. to 25°F. below zero produced an increase in internal resistance of only about 100 per cent.—even at this latter temperature the internal resistance was so low as not to interfere seriously with a light current drain. The indications in this test were that the increase of internal resistance was proportional to the decrease in temperature.

Life tests are often made on dry cells by connecting them permanently in circuit with a fixed resistance. This method is the easiest one to employ, as it requires no attention other than the taking of readings at the desired intervals. Such a test is of no great value, however, as the energy output is small and the life very short unless the current is kept low. Under these conditions the staying qualities of the cell are not demonstrated, and the ability of the cell to stand up under ordinary current drain after a considerable period on "open circuit" service cannot be predicted with safety.

In Fig. 1 is shown the result of tests made on dry cells of the standard 2½ in. by 6 in. size, in which the circuit is closed continuously through a fixed resistance, the resistance in each case being

* Abstract of a Paper read before the American Electrochemical Society.

Digitized by Google

indicated by the figure on the curve. The ordinates give the P.D. at the terminals of the cell and the abscissæ the time in hours. It will be seen from an inspection of these curves that there is a very rapid drop in potential at the terminals of the cell when the resistance is small. As the resistance increases the length of time required to reach any given P.D. is increased. Thus after 10 hours the P.D. at the terminals of the cell has reached 0·5 volt where the resistance in circuit is 1 ohm, whereas with 10 ohms in circuit a value of 0·5 volt is reached after 285 hours.

There is a wide variation in the energy derived from cells under these varying conditions as would, of course, be inferred from the forms of the curves. The value of this energy output in the different cases has been figured to a point at which the P.D. has fallen to 0·5 volt and is found to be as follows:—

With	1 ohm	7 watt hours.	
,,	2 ohms	8	,,
,,	4 ,,	14	,,
,,	6 ,,	21	,,
,,	10 ,,	24	,,

These values would, of course, be modified if the integration were carried to lower points with the lower resistance, but inasmuch as 0·5 volt is only one-third the initial E.M.F., it is seen that we are carrying our energy drain to quite a low point and that the volume of current has fallen to one-third its original value. These curves show approximately what may be expected as the characteristic performance of dry cells under the above conditions.

As we have seen that the "closed circuit" test is not a safe one for "open circuit" work, the best test we can apply is the "open circuit" one in which the cell may be made to show what its life characteristics are when its energy is used over a relatively long period. Sample cells are generally taken for this purpose and tests should duplicate working conditions as nearly as may be. Some form of clock-controlled contacts are very well adapted to this purpose and may be made to control the open and closed circuit periods

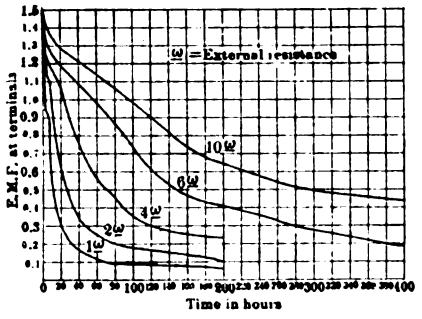


Fig. 1.

in any manner desired. It is also a good plan to use relays controlled by clock contacts for closing the test circuits. By this means, the master or pilot contacts on the clock are only used for light currents, and it is much easier to maintain them in good condition. The mechanism and contacts should be well made and reliable, as it is difficult at best to get consistent results. The shorter tests as a rule give results more satisfactory as regards uniformity than long ones, the chances for variable factors entering being greater with increased time.

In taking readings on dry cells, it is, of course, necessary in either "closed" or "open circuit" tests to have some form of voltmeter to measure the voltage. It is also desirable to use such an instrument for current readings employing the fall of potential method, as this enables current readings to be taken without disturbing circuit connections. If an ammeter is inserted in circuit from time to time, there is a tendency to vary contacts and resistance. Anything tending to introduce variations should be carefully avoided.

In Fig. 2 is shown a set of three curves representing the relation between E.M.F. (curve A), P.D. at the beginning (curve B) and P.D. at the end (curve C) of the closed circuit periods taken from an open circuit test of a standard dry cell. The E.M.F. is seen to be a gradually diminishing quantity, which, however, remains at a comparatively high level. At the instant of circuit closure the P.D. immediately falls and the divergence of curve B from curve A indicates the increase in internal resistance. Curve C also diverges from curve B, thus indicating polarisation during the closed circuit period. The lowest curve is in reality the one of greatest value, for it indicates the level at which the cell maintains its potential under severe conditions. These curves are also of interest as showing what may be expected in the way of internal resistance. The question is often asked as to the magnitude of the internal resistance of dry cells. From the above curves it is seen that there is a continual increase in this quantity as energy is given out. We know also that the internal resistance is very low when the cell is new, for the current on short-circuit is high; as the cell grows older on the shelf the resistance is continually increasing, though to a much smaller extent than when it is on even very light service. In attempting to answer the question, it is necessary to take both these factors into consideration. Hence the requirement for a definite answer is a definite statement of conditions.

In Fig. 3 four curves are shown which are plotted from the results of intermittent tests, each curve representing a special condition. The values are taken from the P.D. at the end of closed circuit periods. As will be seen from the data, curves A and B represent the same external resistance, which is about 1·6 ohms. Curves C and D represent the same conditions, but with 6·6 ohms. Curves B and C represent conditions where circuit closure averages about 0·5 hours per

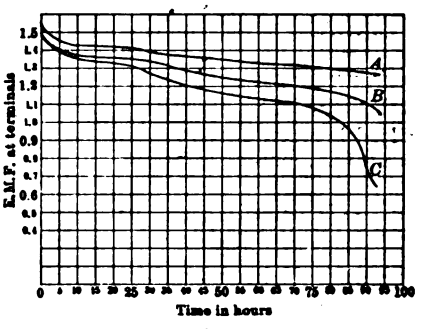

Fig. 2.

day and curves A and D represent an average of about 0·2 hours per day. An integration has been made to an arbitrary point where the P.D. has fallen to 0·7 volt. Where the resistance in circuit is low the watt hours are higher than with corresponding time conditions and high resistance. It seems from this that, down to the integration point taken, cells will give out more energy when allowed to do so at the high rate. At the low rate the energy, th ugh less in watt hours, extends over a longer period of time and the P.D. is maintained at a much higher level. In the tests in which the same resistances are used but the time varied, it will be noted that the watt hours are less with the smaller daily period. This is to be accounted for largely by deterioration taking place over a longer period of time. It is probable that it is due in large measure to the fact that when current is drawn from the cell the action is not uniform; this lack of uniformity would tend to set up P.D. in the cell itself. The result would, of course, be the setting up of local action which would deteriorate the cell to a degree determined by the unbalancing. A degree of unbalancing is to be expected which bears some proportion

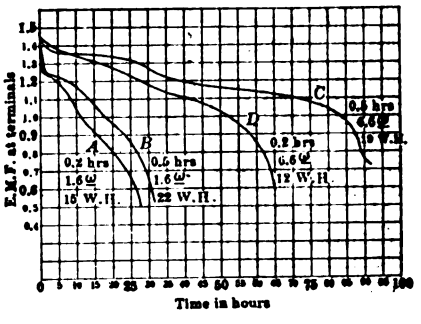

Fig. 3.

to the magnitude of current. The energy of curve A is less than of curve B by about the same amount that curve D is less than curve C, but C and D represent much longer periods of test, hence a smaller rate of deterioration.

In Fig. 4 are two curves which represent tests similar to that shown in curve D in Fig. 3. The conditions being slightly different from that of curve D, the two curves should be compared only with each other. The integration has been carried to 0·9 volt and shows 8·5 watt hours for the longer duration (curve B), as compared to 9 watt hours for the shorter (curve A); the energy, however, in these two cases may be considered as practically identical. We see here the same characteristic of longer duration and higher level with increase in resistance in the external circuit.

In Fig. 5 are shown two curves representing intermittent tests, which are similar to those in Fig. 3, with the exception that in

Digitized by Google

curve A the resistance has been increased to 20 ohms. The duration of the test is approximately one year, and, considering this factor of time, the energy output is very good, the watt hours being about 16 when figured to 0·9 volt. The current drain being light, it is probable that there is small opportunity for irregular action. Curve B is for a still lower current, the resistance being increased to 25 ohms. Although the current is low, the time of closed circuit per day is comparatively long, thus bringing the watt hours up to the comparatively high figure of 30. In integrating curves of this nature, the true value of course lies as a mean between the P.D. at the beginning of the closed circuit period and the P.D. at the end. In these integrations, however, the P.D. at the end of the period has been used because the desire has been to show characteristic action rather than to give exact laboratory data.

Curve C in Fig. 5 represents the result of a test made on ignition service. As no attempt was made to determine the energy, no deductions of this nature can be made. It is, however, of interest as showing what seems to be the requirement for this class of work, and that it is a sustained high potential for the period of its useful life. There are difficulties to be overcome in arriving at any adequate idea of the energy requirements for ignition service. The resistance as well as adjustment of spark coils is very variable and the time of service, as for instance in automobile work, is apt to vary between wide limits. In striving to obtain the highest efficiency, it is necessary to know working conditions, such as current drain or resistance of circuit, and the frequency and duration of circuit closure. Knowing these factors, the proper arrangement for the required number of cells can be made to obtain the best results. It is frequently found that cells in parallel may be advantageously employed for the reason that excessive current drains may thus be avoided. The characteristic action of cells indicates that under heavy current drain the fall of potential is rapid and the energy obtained is small, hence the plan of placing "enough" cells in series may not be advisable;

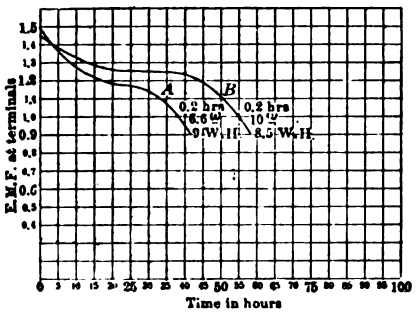

FIG. 4.

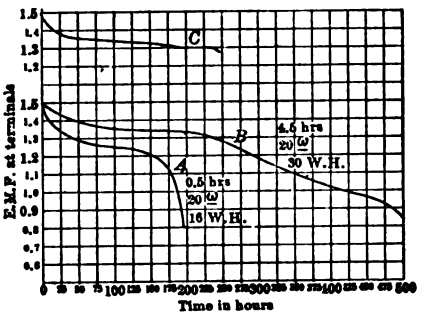

FIG. 5.

an excessive current is of no benefit and on the other hand draws energy in an inefficient way. A high potential may be maintained by placing cells in parallel so that the current drain on each will be light. Such a plan utilises the energy available in a far more efficient way, since we know that at high levels we obtain the greatest amount of energy.

Tests are sometimes made in which a fixed current is caused to flow, but in order to accomplish this, the resistance must be constantly changed. Such tests are interesting, but the conditions are not those ordinarily met in practice. A constant current flow is desirable, however, and a very close approximation to it may be made with dry cells, provided they are arranged for the high level rate of discharge.

One of the important factors in obtaining data from dry cell tests is the "cut-off" point, or, in other words, the value to which the P.D. of the cell may be allowed to fall before it is considered exhausted. The lower a cell is run, the greater will be the energy obtained, but this is offset by the greater variation in P.D. Hence a compromise must be made. A study of conditions must govern the selection of this point in various classes of service, but it should be remembered that it involves one of the most important elements in obtaining best results. The battery gauge is a factor in the situation that must be considered. As a rule, these instruments are constructed as a species of volt-ammeter, in that they are either high resistance ammeters or low resistance voltmeters. As they are not expensive, it can hardly be expected that they will compare favourably with Weston instruments in exactness of indications. The scale divisions generally indicate amperes, and the intention is to show what current would flow if the cell were short-circuited through a low resistance ammeter. The coil of the battery gauge being of only a few ohms resistance, there will be a variation in current depending on the internal resistance of the cell; the deflections of the needle will be approximately proportional to the current strength. When the internal resistance has increased to a considerable extent, the battery gauge is capable of giving a good indication of it. Thus when a cell is exhausted, a battery gauge is convenient and fairly reliable for indicating the condition of the cell. Battery gauges are not reliable for detecting small variations in the condition of a cell, nor for determining accurately any exact condition. Where exact conditions are desired, the best that can be done is to allow the normal working current of the cell to flow and then take a P.D. reading with a standard high resistance voltmeter. Such readings give the best indications of the stage a dry cell has reached in the period of its useful life.

IRON-BAR OVERHEAD CONSTRUCTION AT BROOKLYN.*

One of the most interesting and novel features of the overhead construction of the Brooklyn Rapid Transit System has been the invention and application on a wide scale of iron-bar overhead conductors.

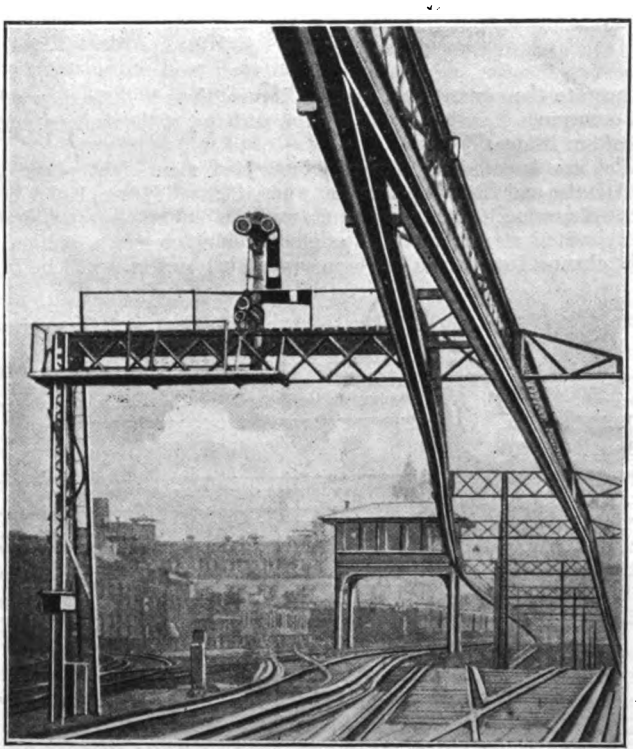

FIG. 1.—IRON BAR CONSTRUCTION ON BROOKLYN BRIDGE SURFACE CAR INCLINE.

These bars are used wherever traffic is heavy and at every important intersection under the elevated railway structure. The adoption of this practice meant a great deal more than the simple suspension of the bars, as it was necessary to design section insulators, expansion joints, frogs, diagonals, feed-in castings and other auxiliaries required to obtain a well-rounded and complete system of overhead construction, All of these details have been worked out with such

* Abstract of an article in the "Electric Railway Journal."

Digitized by Google

success that the iron-bar overhead suspension, wherever used, has proved remarkably reliable and far easier to maintain than methods hitherto regarded as standard. Admitting the reliability of the iron bars for permitting a practically uninterrupted car service, the objection might be raised that they must be very hard on the trolley wheels. This drawback has not been an appreciable factor, however, because the bars are installed only in locations where the traffic is too heavy to operate the cars at high speeds. Hence, there is little chance for the occurrence of severe arcing, except, perhaps, at the inclines on the Brooklyn Bridge.

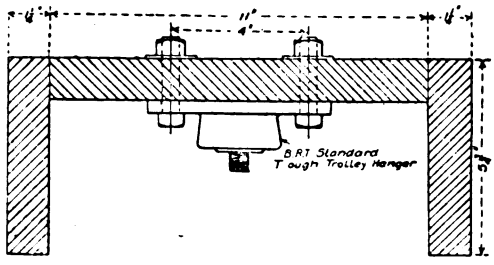

FIG. 2.—TROUGH WORK.

The iron-bar construction was first tried some eight years ago at Atlantic and Flatbush-avenues, where the trolley wire had a very short life owing to the heavy traffic and the limited clearance under the elevated structure. The original conductor was a section of light channel iron, which has been superseded by ⅜ in. by 2½ in. bars of round-edge iron. The latter have been found cheaper than the channels, can be more readily purchased in the open market, and are spliced and installed more easily. In cases of emergency, even a square-edge bar may be installed, leaving the trolley wheels to round off the bar in short order. The bars may be of any commercial grade of iron or steel.

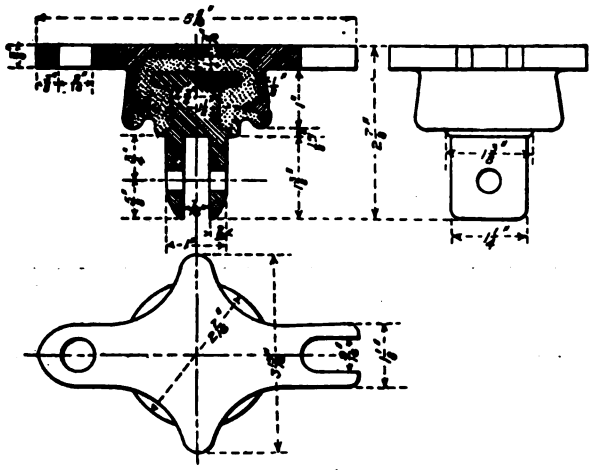

FIG. 3.—TROUGH BAR HANGER.

The bar suspension is also of the greatest value where clearances are so low that the trolley contact has to be offset 4 in. to 6 in. from the centre line in order to permit the cars to operate at all, considering the bending of the trolley poles. An idea of the durability of this work may be obtained from the statement that all the bars at the Brooklyn Bridge terminal on the Brooklyn side have been in use since April, 1908, without change, and are expected to last until February, 1911, at least, whereas even phono-electric wire was not serviceable for more than five months at the same location. At other places frogs and diagonals of the bar design last four to five times as long as those of the composition metal, and cost a great deal less.

All bars are made up in the line department's shops to standard lengths of 16 ft., and are suspended at intervals of 8 ft. Fig. 2 shows the latest form of trough used with this standard bar and hanger. The hanger design permits the use of a lighter bottom-board than heretofore and avoids boring a large hole for the insulating stud, thereby producing economy both in labour and material. The standard trough bar hanger is shown in Fig. 3. It does not differ from the Brooklyn Rapid Transit wire hanger except for the stud.

The composition iron-bar end casting for No. 00 wire illustrated in Fig. 5 is employed to join the overhead wire to the conductor bar.

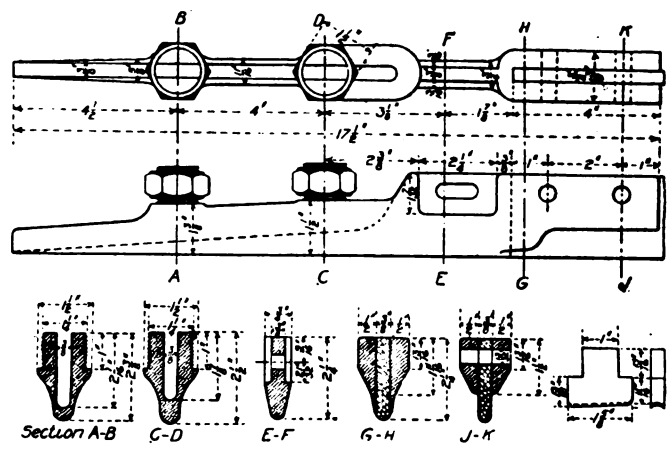

FIG. 5.—COMPOSITION IRON BAR END CASTING.

The casting is riveted to the bar. Means for suspending this casting from the trough are provided by a slotted hole, which allows for the expansion of the bar.

The standard right-hand iron-bar frog (Fig. 4) is designed as an entering frog, and operates properly with all types of cars, whether they have one or two poles, are single or double truck, &c. These frogs are made for standard overall lengths and can be inserted in the conductor bar by removing and replacing six rivets. It has not been thought desirable to use bolts, as the little extra time required to remove the rivets is not objectionable, because generally there is no need for removing the frogs in a hurry, and the changes can be made when it is most convenient. The rivets give better electrical contact than bolts, and none of them has ever been burned out in service.

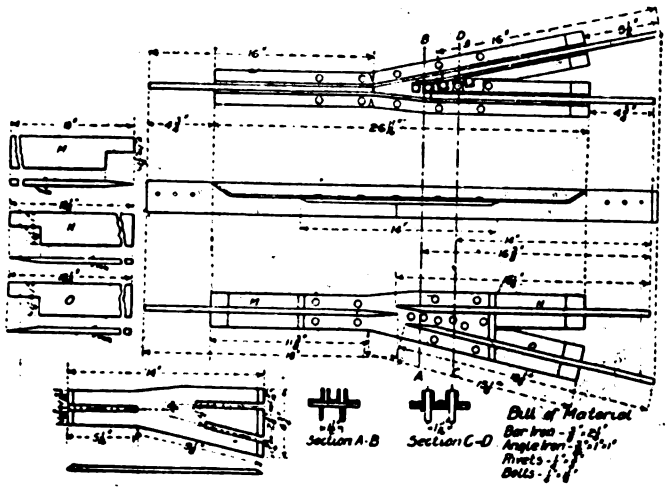

FIG. 4.—STANDARD IRON BAR FROG.

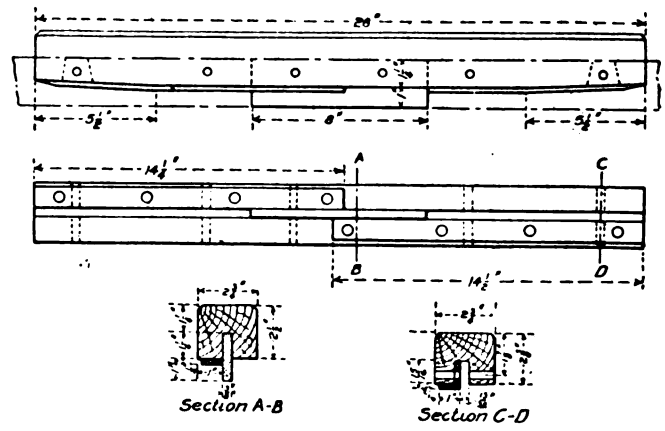

Note.—Wrought iron wearing strips to be fastened, as indicated, with 1-in. No. 10 flat-head screws, countersunk. Insulation—Hard fibre. Wood—Maple or oak.

FIG. 6.—IRON BAR SECTION INSULATOR.

The bar-iron section insulators are made with fibre centres, as indicated in Fig. 6. These devices have given a life exceeding 10 months

Digitized by Google

over the most heavily travelled tracks in Brooklyn. At street intersections it is the practice to put bar section insulators into the trough work to avoid having insulated crossings or section breakers in the trolley wire. The bar method gives a more durable and reliable means of insulating the intersecting lines. The principle of the bar section insulator construction has been applied to the circuit-breakers of the electric automatic track switches operated by the company. These circuit-breakers have been found to last longer than the original designs furnished by the track switch manufacturers.

Side-feed taps are made into the conductor bar by means of a brass casting. This casting has two bolts for the connection to the bar. It is drilled in the upper part to receive a sleeve, into which the copper feed wire is wedged and soldered and then held in place by set screws.

A number of illustrations in the article show typical portions of the overhead construction. Fig. 1 gives a good idea of the equipment.

AN OSCILLATION DETECTOR ACTUATED SOLELY BY RESISTANCE TEMPERATURE VARIATIONS.*

BY W. H. ECCLES, D.SC.

Summary.—The author describes experiments on a detector of the crystal rectifier type as additional support for his hypothesis of the mode of action of electrical oscillation detectors.

In a recent communication to the Physical Society† the properties of a type of iron-oxide coherer were discussed. The Paper described experiments on coherers made by dipping a slightly oxidised iron wire into clean mercury, or by pressing a fine iron wire against a thinly oxidised iron plate, and the results were discussed mathematically. It was shown that in the case of the iron point and oxidised plate the whole of the experiments could be explained qualitatively on the assumption that the only electrical phenomena at play were the Joule effect and the resistance-temperature changes in the small mass of oxide between the metal electrodes.

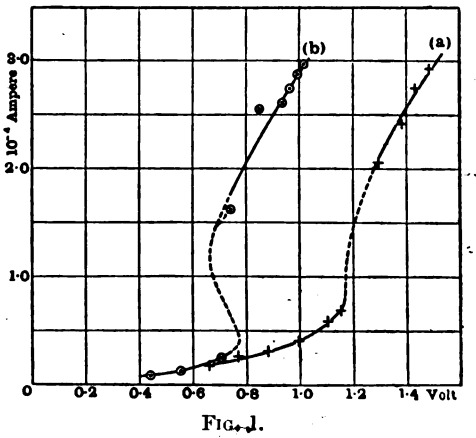

FIG. 1.

The hypothesis that was put forward by the author supposes that a train of oscillations, by yielding its energy as heat to the contact, raises the temperature there and disturbs the existing equilibrium of current and voltage. The dissipation of a train of oscillations is accomplished in a time of the order of a fifty-thousandth of a second; the ensuing fluctuation of the current causes the sound in the telephone. In the Paper cited, the energy w given to the telephone circuit was shown to be connected with the energy W delivered by the train of waves by the equation $w = m(W - a)$, where m and a are constants for any fixed value of the current. This theoretical conclusion agreed well with the experiments on an iron oxide coherer. The object of the present Paper is to show that the above hypothesis holds good for a very different type of detector.

All the well-known forms of "contact" detector consist of a contact between two substances that stand well apart in the thermoelectric series; and the thermoelectric force plays a very important part in their operation. They are usually classed as "rectifying detectors," to distinguish them from such detectors as the coherers. In seeking a "rectifying detector" that would illustrate the above hypothesis, substances that stand far apart in the thermoelectric series must be avoided, for such substances would introduce Peltier effects that would tend to mask the resistance-temperature phenomena we wish to isolate. Even in the iron : iron-oxide : iron coherer it is possible that thermoelectric forces arise owing to unequal heating of the two iron to iron-oxide junctions. It occurred to me, therefore, to construct a detector out of one substance only. Accordingly a search was made for a substance possessing high, but not too high, resistivity, with large negative temperature coefficient. Several such substances were found among the native crystalline oxides and sulphides. Most of these are ælotropic, and must on that account be avoided. Fortunately, galena, the native sulphide of lead, has fairly high resistivity, a very large negative resistance coefficient, and crystallises in the cubic system. A galena-galena detector was therefore constructed. Two pieces of galena cut from the same crystal were embedded in solder, mounted in a clamp and brought into gentle contact. It was put into a wireless telegraph receiving set, and was found to yield excellent signals when a current of proper magnitude was passed through it.

A few preliminary experiments showed that it was not easy to find two pieces of galena which, when placed together and submitted

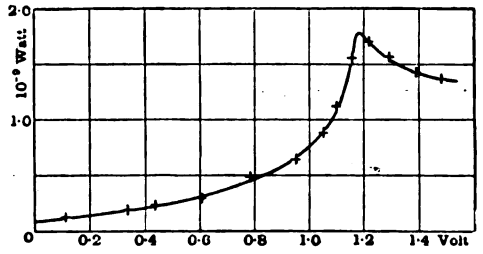

FIG. 2.

to positive and negative voltages in turn, exhibited perfect symmetry. The asymmetry is always small, and is probably due to the rise of thermoelectric forces at the contact when it becomes heated by the steady current, and these forces are probably caused by slight variations in the chemical composition of the galena from point to point in the crystal. When a contact that gives symmetrical voltage-current curves is found, it constitutes a detector that operates only when a current is passing through it. The efficiency of the detector is the same for each direction of the current, and appears to be practically independent of the shape of the galena surfaces at the contact.

The experiments here described were made on selected galena-galena combinations in precisely the same way as the earlier experiments on the iron-oxide detectors. The diagram of the apparatus employed is shown in Fig. 1 of the previous Paper,* and the mutual inductance between L and L′ was 2,500 cm. The detector was submitted to an E.M.F. which was varied in steps from zero to about 1 volt positive or negative. At each step an observation was made

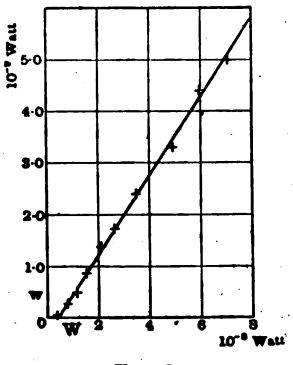

FIG. 3.

of the steady current through the detector, and of the intensity of the sound produced in the telephone. The intensity of the sound was measured by balancing the sound from the detector against that from the interrupter and the potential divider P_3. The curves of Figs. 1 and 2 herewith were obtained in this way. Fig. 3 was obtained by applying oscillations of various amplitudes to the detector while it is traversed by a suitable steady current, and measuring the intensities of the resulting sounds; and therefore expresses the relation between the energy given to the detector and that appearing in the telephone circuit. The curves given are selected out of a number as representative ones.

The most difficult observations to make were the steady current ones. The current-voltage curves obtained with increasing currents are very different from those got with decreasing currents, unless

* Abstract of a Paper read before the Physical Society. A short account of the discussion appeared in our issue of June 17, 1910.

† THE ELECTRICIAN, August 12 and 19, 1910.

* THE ELECTRICIAN, August 12, 1910, p. 724, Fig. 1.

Digitized by Google

certain precautions are observed. Usually a decreasing-current curve lies above an increasing-current curve. The difference between the curves was found to depend greatly on the time allowed for a set of measurements, due to the temperature at the contact lagging behind the changes of current. This temperature lag may be expected to be more pronounced in detectors made wholly of substances of low thermal conductivity than in detectors consisting of a very thin film of oxide between metal electrodes. The phenomenon is very prominent in this new galena detector, though it escaped observation in the iron-oxide detectors, and therefore the former may be expected to work well as a rectifier of alternating currents of moderate frequency. Once the slow movements of heat through the galena had been observed the difficulties were overcome by allowing time for thermal equilibrium to be attained before the final galvanometer reading was taken.

Each setting of the two pieces of galena gives a different contact resistance, and therefore a different curve. Since very slight accidental vibrations can cause relative motion of the pieces of galena, it is almost impossible to perform a series of measurements yielding sufficient data for all the curves of Figs. 1, 2, 3, with full confidence that the contact has not varied.

The galena detector here investigated proves very good in practical wireless telegraphy. It has shown itself to be better than any coherer* known to me. This superiority is, according to the hypothesis here advocated, to be ascribed chiefly to the large negative temperature coefficient of resistivity of galena. By direct measurement of a cube of galena clamped between pieces of tinfoil the resistance was found to fall from 0·33 ohm at 12°C. to 0·10 ohm at 99°C.—a negative coefficient of 0·0079 per degree Centigrade. Pyrites has a coefficient about 0·006. Iron oxide has a coefficient somewhat lower than this last.

NEW POST OFFICE TELEPHONE EXCHANGE AT GLASGOW.

(*Continued from p. 771.*)

The lead covered paper-core cables are led into the building through 50 ducts, 10 from the north side and 40 from the south side. The cables are supported on bearers to the foot of a chute up which they pass to a mezzanine floor above the linesmen's rooms, thence they enter the test room about 3 ft. from the top of the main distribution frame and between the wire chief's desk and the nearest main wall. A general view of the distributing frame is shown in Fig. 6. The solid joints between the paper core cables and the silk and cotton core cables are staggered along a support which runs the whole length of the main distribution frame. This latter frame, together with the meter and relay racks, are designed and grouped for ready extension when necessary. This facility is ensured by arranging the apparatus vertically on both sides of the racks.

The line, or fuse, side of the main frame has a circuit capacity of 16,560 lines grouped upon 69 verticals of 240 each; the exchange side, accommodating the heat coils and lightning protectors, has a capacity of 13,800 circuits, comprising 69 verticals of 200 each. In cabling the main frame the lead is stripped from the silk and cotton core cables, and 12 groups of 20 pairs are formed for the 12 fuse mountings. The bunch of 40 wires pass behind and within the horizontal channel iron to which the mounting is fixed, and are accordingly protected from the cross-connection field. Fire risks are minimised by placing sheets of uralite underneath each horizontal layer of the cross connection field. The meter rack will accommodate 10,200 meters and each relay rack will carry 5,400 line and cut-off relays; the intermediate frame has a capacity of 12,400 circuits. To afford access to the main frame and racks travelling ladders are provided.

A diagram of the connection of the ringers is shown in Fig. 7, there being two belt-driven ringing generators, one connected to a 40-volt direct-current motor and the other to a 250-volt direct-current motor. Each generator shaft carries a divided ring from which the positive and negative pulsations are obtained for the operation of party lines. To the same shaft are also fitted two high-speed tone interrupters, giving respectively 400 and 133 vibrations per second; the former is employed for the busy back and plugging circuits, and the latter for trunk tone test upon incoming junctions. The diagram shows a number of slow-speed interrupters, which are driven at 1/30th the speed of the generator by means of gearing.

The transmission system adopted is illustrated by the diagram (Fig. 8). This will be noticed as a modification of the

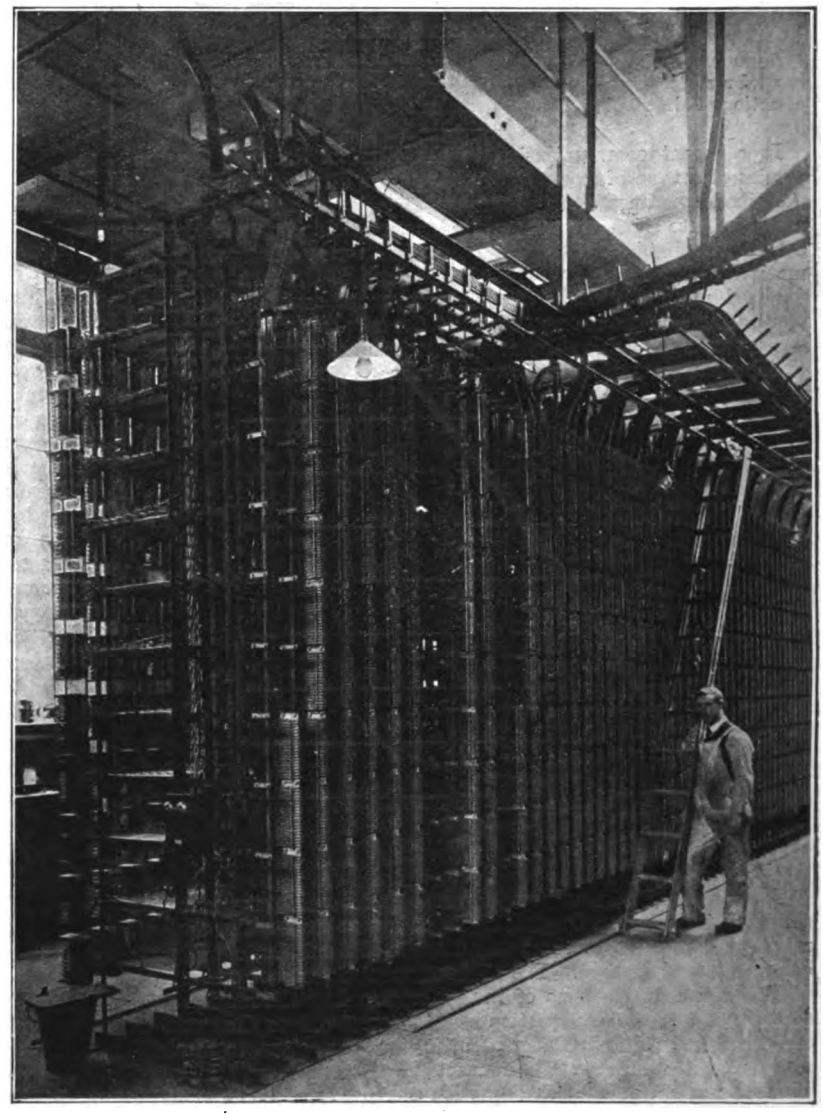

Fig. 6.—Distributing Frame.

method devised by Mr. J. S. Stone in 1892. The 40-volt common battery is coupled to the tip and ring conductors of both sides of the cord circuits by way of 200-ohm supervisory relay coils. The two 2-tip and two ring conductors of the plugs are connected through two 2-mfd. condensers. It is claimed that an exceptionally silent system is obtained by this method, and that greater sensitiveness in the relays is secured by the use of the higher voltage. Interesting new features in the subscribers' line circuit are the 40-volt line lamp, 50-ohm cut-off relay and the double coil line relay. In view of the fact that small private branch exchanges, which require current from the "B" wire exchange circuit, not being catered for in Glasgow, a 200-ohm line relay coil can be used between the nega-

* But not so good as certain "thermoelectric" detectors.

Digitized by Google

tive pole and the common battery and the "B" wire of the circuit. For the same reason a 200-ohm supervisory relay coil in the cord circuit may be used to connect the common battery to each "ring" conductor. The composite diagram shown in Fig. 9 gives the subscriber's line and operator's keyboard connections. It was the original intention to provide a composite supervisory relay for each side cord circuit, but this was abandoned for the more simple arrangement shown. When the calling subscriber removes his receiver the line relay circuit is closed, and the 40-volt line lamp is connected across the multiple jack socket would have been at zero potential and no click would have been heard. The subscriber required is called by the insertion of the calling plug and the intermittent throwing of the ringing key. The cut-off relay of the circuit required is energised and the line relay and the line lamp of that circuit are cut out. While ringing continues the 36-volt supervisory lamp in connection with the supervisory relay will glow, and ringing is proceeded with until the supervisory lamp darkens. The removal by the called subscriber of his receiver closes the circuit for the calling supervisory

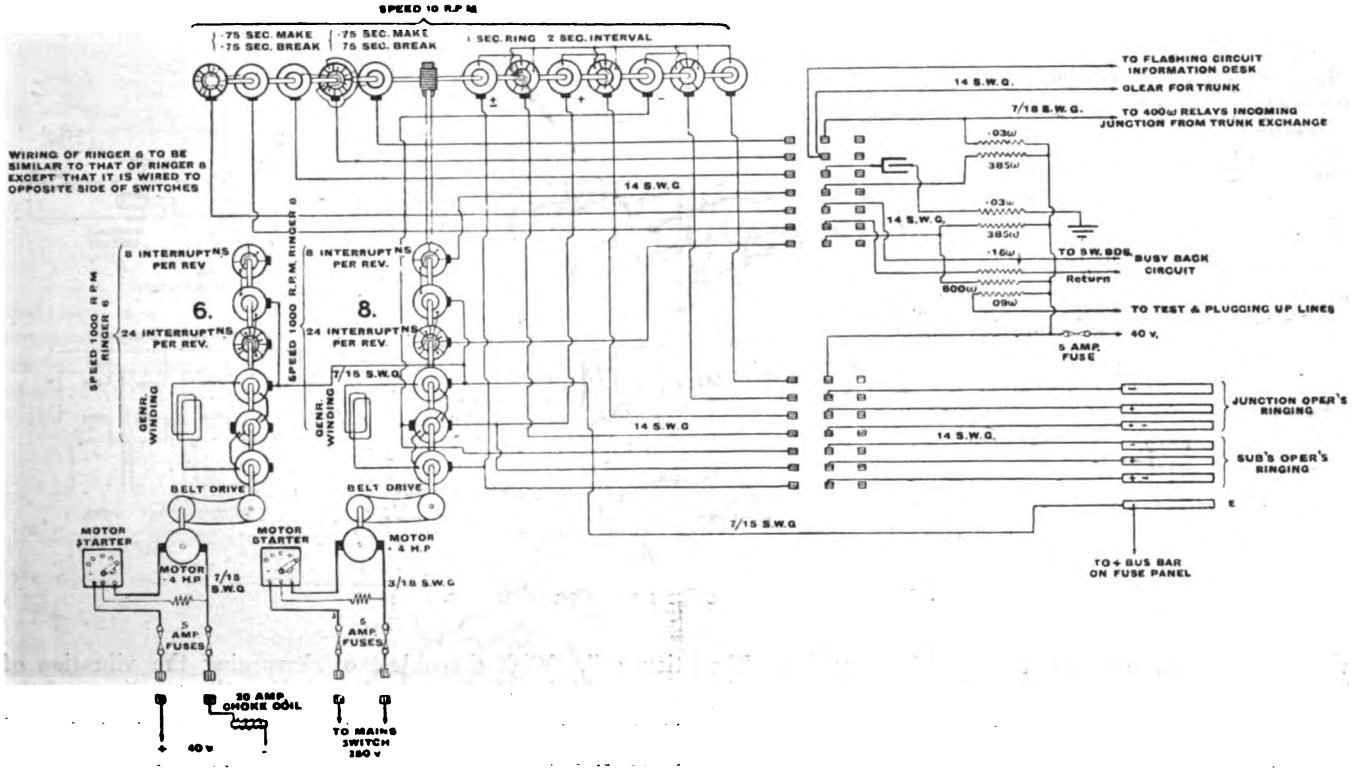

FIG. 7.—CONNECTION DIAGRAM OF RINGER CIRCUITS.

the common battery. The answering plug of the disengaged circuit is then inserted into the answering jack. The cut-off relay is then energised through a 400-ohm resistance in the cord circuit, and the line relay is disconnected from the calling subscriber's circuit. The circuit for the answering supervisory relay is also closed, and the 36-volt supervisory lamp actuated by this relay is disconnected. The number required is taken by the operator through the speaking key, and the tip of the calling plug is placed in the nearest multiple jack of the subscriber required. If engaged, a current will be flowing through the cut-off relay of this circuit, and as all multiple

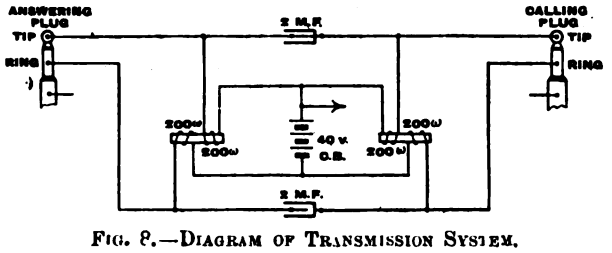

FIG. 8.—DIAGRAM OF TRANSMISSION SYSTEM.

jacks are in multiple with each other and the answering jack, a negative potential will exist at the jack sockets of each engaged circuit. When the speaking key is thrown, the tip of the testing plug being at zero potential, the charge in the condenser is proportional to the full voltage of the battery. When the tip of the testing plug and the socket of the engaged line are brought into contact, the voltage across the condenser is reduced and a discharge follows through the operator's receiver and an audible click is produced. If the circuit required had not been engaged relay. During the conversation both supervisory lamps are out, and the current consumption is thereby reduced to a minimum. The subscriber who originated the call controls the answering supervisory lamp, and the called subscriber the calling supervisory lamp, thereby affording double supervision. When both receivers are hung up the circuits of both supervisory relays are broken, both lamps glow, and the operator, after depressing the meter key for effective calls, disconnects the lamp circuits by removing the plugs from the jacks.

The arrangement of the meter circuits is similar to that employed by the Post Office department in London and Cardiff. The connections for these circuits are incorporated in the diagram (Fig. 9). The arrangement is distinctive in that no extra cells are required, the meters being operated from the common battery circuit. The meter circuit for effective calls is in two sections, one for the subscriber's line and the other for the answering side cord circuit; these are connected when the answering plug is inserted into the answering jack. A meter key is provided for effective calls for each answering plug, and an operator's or position meter with lamp is furnished for each "A" position. The resistance of the position meter is 0·5 ohm, and the low resistance winding of the subscriber's meter is 50 ohms. When the answering plug is inserted in the answering jack, current flows from the 500-ohm winding of the meter and also through the cut-off relay winding. Until the meter key is pressed the current in the 500-ohm winding is too weak to actuate the meter armature, but the depression of the key shunts the 400-ohm resistance and 36-volt lamp by the 0·5 ohm winding of the position meter. This increases the current in the 500-ohm winding six-fold, and the armature is attracted and the meter reading advanced by 1 unit. The movement

Digitized by Google

of the armature also couples the 50-ohm winding in multiple with the 500-ohm winding, halving the resistance in series with the position meter, the latter causing the meter lamp to glow and adding 1 unit to the position reading. The position meter records all effective calls handled by the operator, and the subscriber's meter all effective calls originated by him. Provision is also made at each answering position for a special meter key and meter for the recording of ineffective calls.

The common battery is employed to supply current to the operator's transmitter, the necessary reduction of voltage across the transmitter being obtained by a 400-ohm retardation coil. With the object of sharpening the vibration of current in the 11-ohm primary winding, this winding and the transmitter are shunted by a 2-mfd. condenser. The combined action of this coil and the condenser shields the operator's telephone circuit from cross-talk and other disturbances. The existing practice of the department has been followed in the

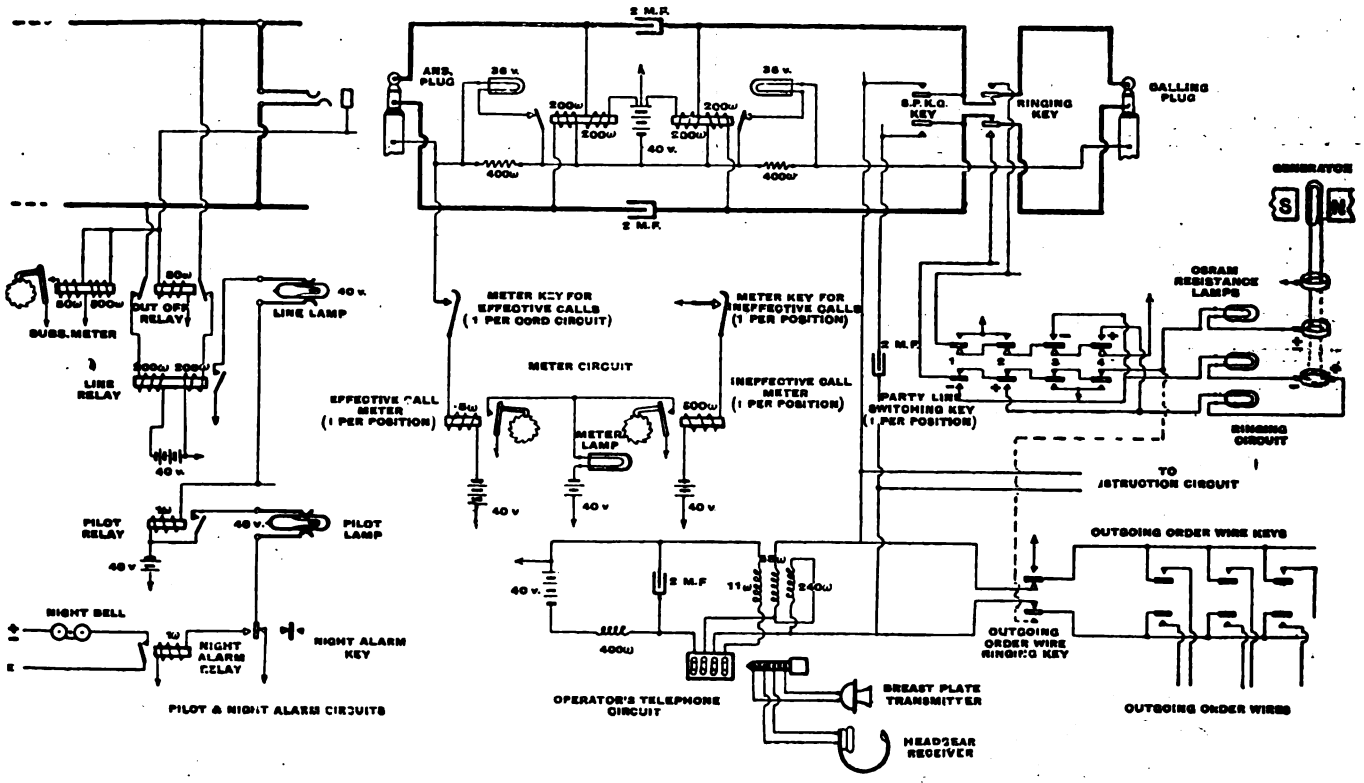

FIG. 9.—SUBSCRIBER'S LINE AND CORD CIRCUITS.

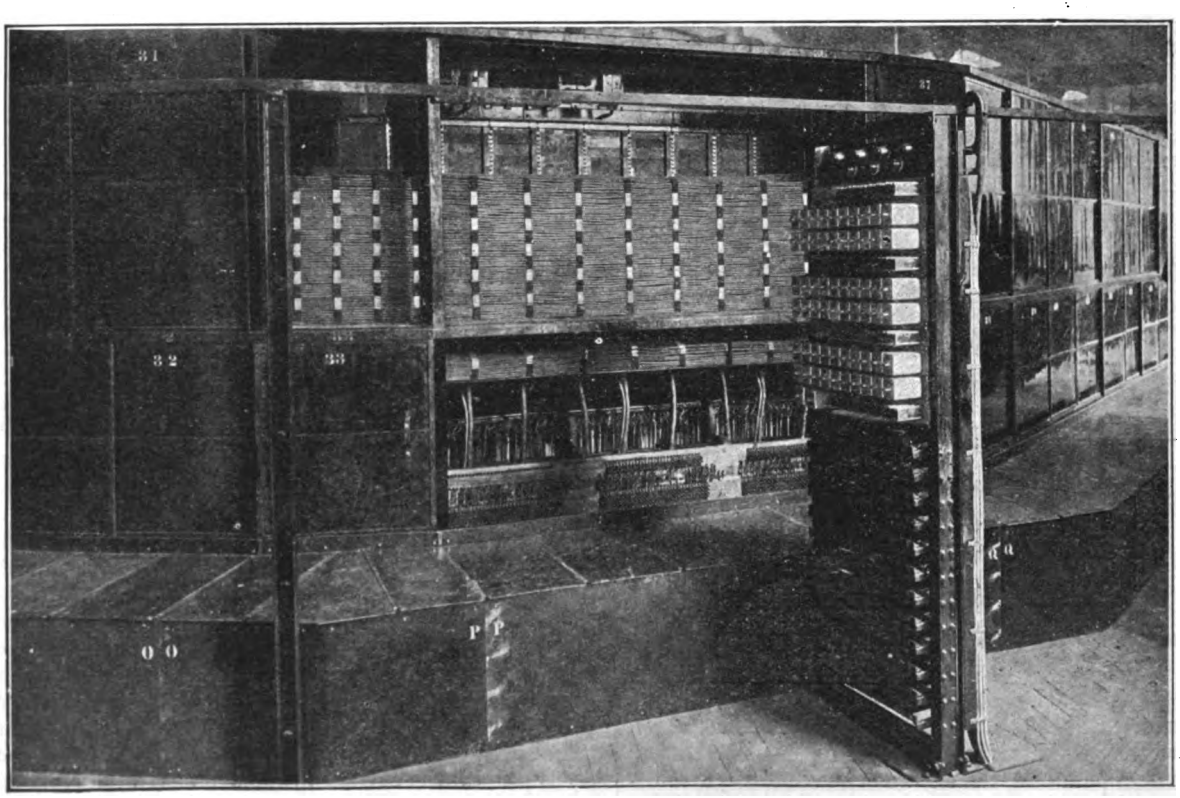

FIG. 10.—SUBSCRIBER'S BOARD, REAR VIEW

method employed for the diminution of "side tone" in the operator's receiver. The 58-ohm or tertiary winding acts as the secondary winding, while the 240-ohm winding is coupled across the receiver, so that while its action assists the 58-ohm winding in the subscriber's circuit, it opposes that winding in the operator's receiver. Each operator's position is provided with a set of four-party line switching keys on the Thompson and Robe system. This system requires that between the pulsations the brushes bearing on an additional two-segment ring fitted to the generator armature and collecting the positive and negative pulsations respectively shall be

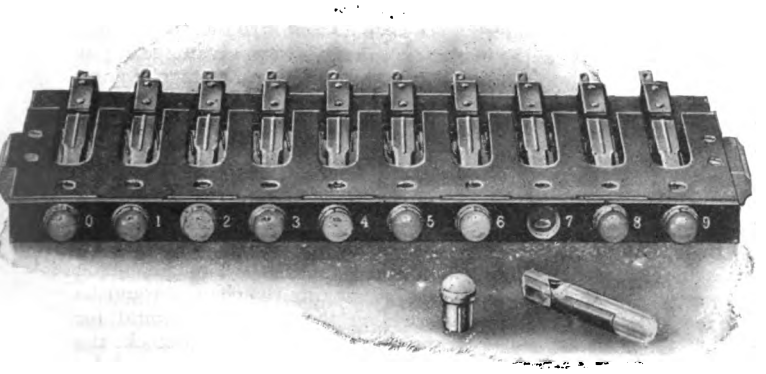

FIG. 11.—LAMP JACKS, SHOWING ONE OPAL CAP AND LAMP WITHDRAWN.

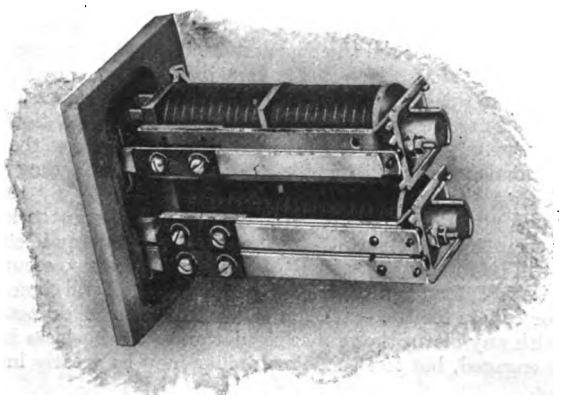

FIG. 12.—LINE RELAY (AT TOP) AND CUT-OUT RELAY.

connected to earth. This is done by coupling the spare segment of the divided ring to the earth ring by an internal insulated conductor. Three resistance lamps are fitted to each subscriber's position to prevent too great a demand being made on the ringing generator when this is coupled to a faulty circuit.

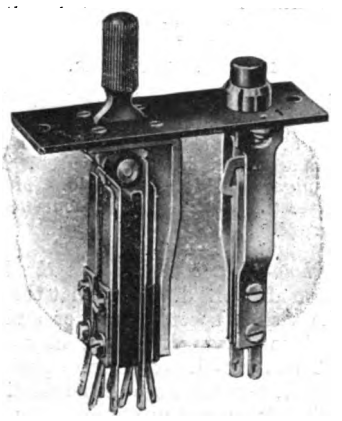

FIG. 13.—RINGING AND SPEAKING KEY.

Osram lamps, which have the advantage of a positive temperature coefficient, have been employed for this purpose. Fig. 10 shows a rear view of a portion of the subscriber's board.

The wiring of the subscriber's line circuit has been divided into nine important sections, representing connections at the main distribution frame, the relay rack, the intermediate distribution frame, the multiple junction board, the multiple subscriber's board, the meter rack, the fuse cabinet, the apparatus rack at the rear of the subscriber's board and the answering position. On the line side of the main frame the G.P.O. standard 3-ampere glass tube fuses are utilised. On the exchange side of the main frame are assembled the lightning conductors and the heat coils. The relay racks are erected between and parallel to the main and intermediate distribution frames, so that the 42-wire cables can be conveniently and economically terminated upon the relay rack instead of at the intermediate frame as was previously the practice.

Figs. 11, 12 and 13 show details of the most interesting items in the subscribers' sections.

(To be concluded.)

TWENTY FIVE YEARS OF CENTRAL STATION COMMERCIAL DEVELOPMENT.*

BY S. INSULL.

In 1885, when the National Electric Light Association was formed, the development of the central station business was confined almost entirely to a few companies established under the auspices of the Edison Electric Light Co. The companies forming our early membership were not engaged in what we understand to-day as central station business, but were either arc light manufacturers and supply men, or those companies who were engaged in series arc lighting, doing practically no other business, except in a very few cases a small amount of power and series incandescent business. At the Niagara Falls meeting, in 1897, I well remember the Paper read by Mr. T. C. Martin on the "Daylight Work of Central Stations." He started his Paper by stating that the central station industry had in some respects been a disappointment, that after nearly 20 years of work the companies restricted themselves injuriously by remaining mere lighting companies, and he asked the question, What would become of the central station companies if a new lighting medium came into vogue and we were deprived of our illuminating business entirely? To get statistics of the early days of the business is a difficult matter, but Mr. Martin showed that in 1886 there were 410 central stations in the country, that only 300 of these furnished any statistics, and that of these 226 were only doing a night business. Assuming that those who did not report were in the same class as the 226 doing only a night business, we find that out of 410 so-called central station companies 325 were doing business only between dusk and daylight.

It is probable that to say £2,000,000 represented the cash investment in the business in 1885 is naming a very liberal amount, whereas it is authoritatively stated that between £200,000,000 and £250,000,000 represents the total sum of the capital employed to-day in the central station industry of this country.

The commercial development of the business was of necessity in the early days hampered, amongst other things, not only by a lack of knowledge of conditions governing the relation of the true methods of selling electric energy to the cost of producing it, but also by the high capital cost of the plant used. The leading features which, from the technical and engineering side, have made the central station business of to-day possible, are the change from the two-wire system to the three-wire system; the reduction in the energy consumption of the incandescent lamp from 6½ watts per candle in 1882 to $3\frac{1}{10}$ watts per candle in 1890; the introduction in 1886 of the alternating-current system (making the central station business available for the small towns throughout the country); the building in 1890-1891 of slow-speed electric generators directly connected to highly economcal reciprocating engines (the first step in reducing the cost of central station investment and the operating cost of the energy produced), followed in 1896 by the introduction into this country of the use of high-tension alternating transmission lines operating sub-stations. The combination of the above forced, on account of the saving made, the abandonment of small generating stations and the massing of production on a very large scale. The limit of the size of units of power was reached by reciprocating engines at about 5,000 H.P., and the increasing demand for energy resulted in the development of very large steam turbo-generators, which operate to-day in units of upwards of 20,000 H.P., and which will within the next year be operating in units of 30,000 H.P. Moreover, within the last two years the introduction of higher efficiency incandescent lamps has greatly reduced the cost of light.

In the early days of the development of the central station business—from, say, 1881 to 1891—the customers of the central station companies looked upon our product as more or less of a luxury. Rates were very high and the result was that business was confined almost entirely to short-hour consumers, the interest and operating costs to the company being necessarily very high. It was not until the early nineties that any of the managers of the large central station properties of the country appreciated the fact that if they desired to place their business on the basis of a general public necessity it was necessary for them to rearrange their rates on such a plan as would give the long-time consumer the lowest possible price. The recognition of the necessity of meeting this condition may possibly have had as much to do with reducing operating cost and reducing interest and depreciation costs as have the wonderful work of the inventors and the marvellous skill of the engineers.

I am dwelling upon this subject, not with any idea of belittling the great achievements of inventors and engineers, but for the purpose of impressing, more especially upon the younger men connected with our organisation, the great importance of the commercial side of the business, and to point out to them the advantage alike to themselves and the business itself of their bestowing upon the commercial side of the business as much, if not a greater amount of thought than that which they bestow upon the technical operation and construction side of central station development.

The possibilities of central station business, while great to-day, must be far greater in the future, and in trying to point to what those possibilities are it might not be amiss to discuss what is the real function of a central station company. Is it simply to light the streets of the city, as most of the electric lighting companies thought was their function 25 years ago? Is it merely to do house-to-house lighting, as was (with the incidental power connected with it) the business inaugurated by the few Edison companies a little more than 25 years ago? Should a central station company be engaged merely in production of power for industrial purposes, or for railway purposes—whether the railway be urban, inter-urban, state or interstate? Or should the central station company embrace all of the functions stated above and produce all of the electric energy needed in a given community or a given area?

The maximum load of the electric lighting business in this latitude comes in December, and is accentuated by the industrial power load; the maximum load of the street railway business comes more often in January than in December, especially in the central west, owing to the conditions of temperature and consequently heating as well as traction. The maximum load of the steam railway business, so far as I have been able to figure it, comes in the middle of the summer in Connecticut and Massachusetts, towards the end of September around New York City, and in October around Chicago and St. Louis. The maximum load of a waterworks comes in a great many instances, if ample storage is at an elevation, at the convenience of the producer; and, in any event, it comes at a time of the year when the demand for total energy used in a given community for other purposes is by no means at its maximum. Why should all these operations for the production of energy be dealt with on a separate basis? Why not concentrate them all, and by so doing get low cost of production, low capital investment (because of the elimination of duplication of investment), and increased diversity of demand for energy, and, what is of vast importance, consequent low prices to all users.

What I am advocating is merely the extension of the central station idea. If you will apply the arguments that you use to persuade a possible customer to give up his isolated plant to the larger questions of manufacturing and distributing electric energy, you must come to the conclusion that our true function as central station companies is not only to supply the energy required in the community in which we live, but also to supply the energy required to carry us to the next community when we go to visit our neighbour, or, in any case, to carry us part way.

The vice-president of the New York, New Haven & Hartford Railroad recently said that, in his opinion, within the next 15 years the New Haven road between New York and Boston would be electrified throughout, and the towns on the way would have the opportunity of obtaining electric energy at a very low cost, the cost dependent upon the cost to the railway company of current, which, in his opinion, would necessarily be low because of the very large amount of business that they would have of their own. The work of the New York Central and Pennsylvania railroads in the way of electrification has gone hand in hand with the work of the New York, New Haven & Hartford Railroad, and if the steam railroad people look forward to current being supplied at very low cost throughout Connecticut, Massachusetts and Rhode Island as a result of the production of current in large quantities for the electrification of the steam railroads in those States, the same thing must necessarily happen throughout the whole of the densely settled portion of the United States if the reasoning of the vice-president of the New Haven Railroad be correct.

But it would seem to me that our functions as producers of electric energy should, with the tendency towards electrification of steam railroads, become very much broadened, and instead of its being the exception, as it is to-day, for a central station company to cover any large amount of territory outside of the municipality in which they are mainly established, their operations will become far more extensive; since, if the steam railroad men of the country want electric energy produced economically, they should find it to their advantage to come to us as specialists in electric energy, taking advantage of our experience in the best methods to pursue, taking advantage of combining their necessities for electric energy with the necessities existing in the communities in which we operate—which combination will result in economies which neither can obtain separately—and so leading to the establishment of large central station plants capable of supplying all the requirements in the way of electric energy for a large area of territory surrounding the centres of population. If our members will do their share towards working to such a desirable end the possibilities of electrification of steam railroads will be brought much nearer to us. The financial burden of making the change would be divided, the steam railroads providing the necessary capital for electrifying their right of way and changing their rolling stock, the central station companies of the country providing the capital for building the large generating stations and transmission lines to convey the electric energy to the railroads and other consumers along their right of way.

As to the relations of the central station business and the communities, the business in which we are engaged can be most successfully operated as a monopoly. If the communities which we serve are to get electric energy at the lowest possible cost, they can only expect to achieve this by preventing duplication of investment and by concentrating production under one organisation. It should be borne in mind that the more closely our business is supervised and regulated the greater are the chances of our being protected against ruinous competition, which to-day is mainly instigated by those who desire to take this means of acquiring our existing business. Whilst we may not care to be hampered by the rules and regulations established by commissions created to watch over our operation, the further these commissions go into our business the more will they be convinced that the best results can be obtained only by regulated monopoly, and that competition is alike as ruinous in the long run to our customers as it is to the central station company itself. The result will be that our monopoly of the business will be secured, our securities will stand in higher credit and new capital will come flowing into our coffers for the extension of our business. I do not myself view with any alarm the proper regulation of the business in which we are engaged, but feel that its stability may be greatly increased thereby.

President Insull next referred to the desirability of fostering a friendly feeling of relationship between the supply company and its customers, and concluded with an appeal to the young men to look upon their chances for success in the central station field as of the highest possible opportunity.

PHOTO-ELECTRIC PROPERTIES OF THE ALKALI METALS.*

BY F. K. RICHTMYER.

Summary.—In the first section of this article, which is a continuation of previous researches, the author describes experiments to ascertain the dependence of photo-electric current on the wave-length of the incident light, an acetylene flame being used. In the second part of the article he suggests useful applications of the photo-electric properties of alkali metals, such as the measurement of the decay of phosphorescence.

Dependence of Photo-Electric Current on the Wave-length of the Incident Light.—Soon after the discovery that the alkali metals were photo-active in the visible spectrum Elster and Geitel published some brief observations showing the sensibility of these metals for different colours. These data, however, were qualitative rather than quantitative, and as the exact nature of the relation between wave-length and photo-electric current would not only be of value in the theory of photo-electric phenomena, but would also help in correlating it with other phenomena, the writer has attempted the determination of this relation for sodium—which has a maximum of sensibility in the visible spectrum. The apparatus used has already been described in a former article,† the only modification

* Abstract of two Papers read before the American Physical Society.
† THE ELECTRICIAN, March 4, 1910, p. 859.

Digitized by Google

being that the source was replaced by a spectrometer, whose movable telescope arm carried the source of light, the spectrum of which was to be thrown on the sensitive surface of the photo-electric cell. The spectrometer was calibrated by the lines from a mercury vapour lamp. The prism gave a spectrum about eight degrees in width. The widths of the two slits were equal and represented about 10 minutes of arc. As before described, the platinum wire leading to the sensitive surface was charged to such a negative potential as to reduce the leakage current, through the walls of the cell, to zero, thus making the photo-electric surface at zero potential with respect to the receiving Pt wire. Under these conditions the rate of deflection of the electrometer was proportional to the photo-electric current.

A Nernst glower was at first used as a source. Although this furnished a very intense light the glowers did not last long enough for making a good set of observations. An acetylene flame was then substituted and had a twofold advantage. Not only was it of constant intrinsic brightness, but also the energy distribution was known, having been recently determined by Profs. Nichols and Merritt.*

In order to make the results useful for comparison two corrections were made: First, due to the variable dispersion of the prism, it was necessary to reduce the observed photo-electric currents to what would have been obtained had the spectrometer slit included a constant number of wave-lengths at each observation. The slit width was such as to make it possible to do this by graphical means from the slope of the calibration curve of the spectrometer. Second, the final relation between wave-length and photo-electric current should show the current that would be produced by the same amount of energy at each wave-length. This correction was made

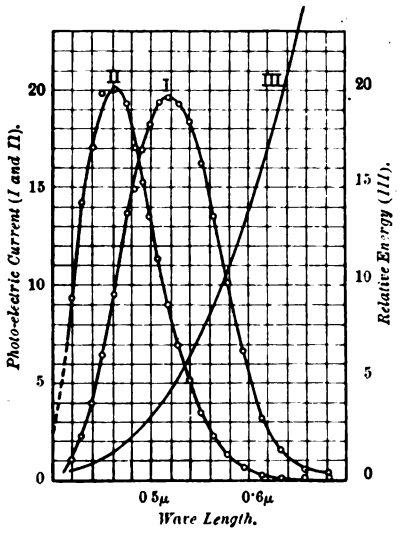

FIG. 1.

by dividing the observed currents by the relative energy for each wave-length in the spectrum of acetylene. As the above curve of Nichols and Merritt for the energy distribution extends only as far as 0·48μ, while the observations in this experiment extend to 0·42μ, a method of extrapolation was employed, using Wien's equation for the energy distribution in the spectrum of a black body,† a new energy distribution curve being obtained, extending to 0·42μ (*see* Fig. 1, curve III). The observed photo-electric currents, after making the correction for variable dispersion are divided by these energy values. The resulting currents are those which would have been obtained from a normal spectrum containing the same amount of energy for each wave-length. The results are shown in Fig. 1, curve I. being the observed curve, and II. the curve after making both the above corrections.

The significance of the exact shape and location of this curve for sodium is not at present apparent. The maximum occurs at about $\lambda = 0{\cdot}46\mu$, and yet $\lambda = 0{\cdot}46\mu$ does not seem to bear any unique relation to any of the known properties of sodium. Still some relation must exist. There must be some reason why a sodium surface shows a maximum at one wave-length, and rubidium, for example, at another. If such a relation could be established it would doubtless do much to explain not only photo-electric phenomena but also many questions connected with the structure of matter.

Whatever theory of the photo-electric discharge we accept the shape of the above curve is very strongly suggestive of resonance in some form or other, and that the expulsion of the electron is due to selective absorption of light. If such is the case the free period of the electron in the sodium atom in its solid state should be determined by the period of vibration for $\lambda = 0{\cdot}46\mu$, and metallic sodium ought to show selective absorption for this wave-length. But since the curve extends over a comparatively large range of frequencies, the question might be raised whether the frequencies of the electrons are correspondingly distributed, or whether all the electrons have the same frequency and the effect of light other than $\lambda = 0{\cdot}46\mu$ is due to vibrations of a semi-forced nature. Further experiments along this line are in progress.

Apropos of the present discussion as to whether the energy of the expelled electron comes from an atomic explosion under the influence of light or from the absorption of energy from the incident light,* it might be of interest to consider the energy changes involved. Unfortunately data are available for only the roughest kind of an approximation, but the magnitude of the quantities concerned can at least be shown. In a recent experiment by the writer† a sodium surface containing 10 square cms. was exposed to the radiation from a 2,000 c.p. arc at a distance of something less than 1·5 metres. If we assume the reflecting power of sodium as given by Drude (for white light?) to be 99·7 per cent., we obtain, after making due allowance for other absorptions and reflections, that approximately 400 ergs per second of light energy are absorbed by the sodium surface. Comparing the above distribution curve with the visibility curve we might conclude that 100 ergs per second of this energy fall within those wave-lengths which are capable of producing the discharge.

The photo-electric current resulting was 25×10^{-9} amperes, corresponding to 25×10^{10} electrons per second if we accept the value of e as 10^{-20}. In the article cited, Kunz has found the initial velocity of the electrons from a sodium-potassium alloy to be 6×10^{7} cm./sec.

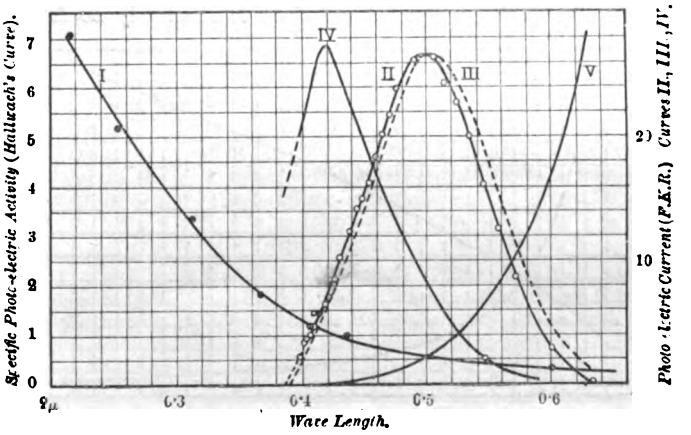

FIG. 2.

for $\lambda = 0{\cdot}42\mu$. The velocity of the electrons from the above sodium surface can hardly be more than 10×10^{7} cm./sec., giving as the kinetic energy per electron 3×10^{-12} ergs, where m is taken as 6×10^{-28} grams. This makes the total kinetic energy of the expelled electrons 0·75 erg per second, a quantity which so far as its magnitude is concerned could easily be supplied from the 100 ergs per second of absorbed energy.

Since the above was prepared for publication, Hallwachs‡ has published some data showing the "specific photo-electric activity" for potassium from 0·2μ to 0·6μ, using the lines of the mercury arc in quartz as the exciting source. Excluding the existence of secondary maxima, his data, when plotted as a smooth curve, take the form shown in curve I. Fig. 2. It was suggested to the writer that the radical difference between this curve and Fig. 1 (II.) might have been in part due to the use of a flint glass prism, which undoubtedly did absorb some of the energy in the blue and violet region. It did not seem possible, however, that this absorption could have been sufficient to account for the difference.

It is to be regretted that measurements of the energy distribution in the spectrum of acetylene in the neighbourhood of 0·4μ are almost impossible. However, to test in a qualitative way the influence of absorption, the flint glass prism was replaced by a carbon bisulphide prism, which is especially transparent to the blue and violet, and the measurements repeated. The results are shown in Fig. 2, curves II, III. and IV. Curve II. is plotted from the

* "Physical Review," Vol. XXX., p. 328.

† This method is, perhaps, not altogether justified, since we are not sure that acetylene follows Wien's law of radiation exactly. It was used, however, with the hope of checking it up later.

Digitized by Google

observed data without making any corrections. The ordinates, as in Fig. 1, are rates of deflection of the electrometer in millimetre per second. It is to be noted that the maximum ordinate is only a trifle over one-tenth of the corresponding ordinate in Fig. 1 (II.). This is due to smaller light intensity. A slight correction to curve II. is necessary on account of the rapid change of the index of refraction of CS_2 with change of temperature. Fig. 2 (III.) is the result of this correction, the points being omitted to avoid confusion. Finally, after reducing to a normal spectrum with equal energy distribution, we get Fig. 2 (IV.).

The maximum persists although, as might be expected, it is shifted somewhat toward shorter wave-lengths. Still it seems sufficiently prominent to call it a primary rather than a secondary maximum, the exact location of the crest being somewhat in doubt. In other words the use of the flint glass prism seems to have shifted the curve rather than changed its form.

In conclusion, the extreme sensibility of the photo-electric cell, even at zero potential, may be mentioned. In these later experiments, the shape and size of the CS_2 prism was such as to necessitate cutting down the beam of light through it to a few millimetres diameter. The light emerging from the collimator, when allowed to fall on a piece of white cardboard, was scarcely visible even in a dark room. And yet the photo electric currents produced by it were measured without much difficulty. This is more strikingly illustrated by reference to Fig. 2, (V.), which shows the relative energy for each wave length falling on the cell, taking into account the variable dispersion of the prism.

Laboratory Applications.—While performing some photo-electric experiments the writer was greatly impressed with the possibilities of putting this phenomena to various laboratory uses where optical measurements by eye are either extremely difficult or altogether impossible. For example, as a photometric device for monochromatic light a sensitive sodium surface excels the eye in several respects; (1) In a properly constructed cell there is absolutely no fatigue.

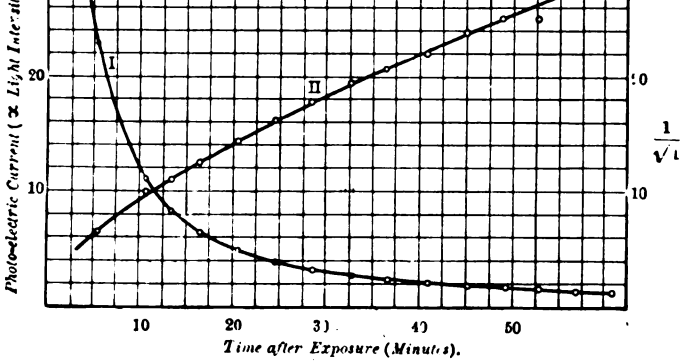

FIG. 3.—PHOSPHORESCENCE OF BALMAIN'S PAINT.

(2) The greatest sensibility is in the blue and violet region, where the eye is least sensitive. (3) The magnitude of the photo-electric current, *i.e.*, the sensibility of the device, can be increased by (*a*) increasing the area of the sodium surface, (*b*) increasing the area of the photometric field, and (*c*) decreasing the distance of the field from the sensitive surface; whereas the action of the eye depends simply on the intensity of light in the photometric field. In a photometer little gain in sensibility results from increasing the size of field, or, within limits, of moving the field nearer the eye.

A case in point is the measurement of decay of phosphorescence. A sample of Balmain's paint on a visiting card was exposed to sunlight for 30 seconds, and then placed over a window about 8 cm. in front of a sodium surface, so that 10 or 12 sq. cm. of the card were exposed. At first the rate of deflection of the electrometer was too rapid for accurate measurement. After about six minutes, however, observations were begun and the rate of charge taken about every four minutes, continuing for one hour after exposure. The results are shown in Fig. 3 (I.). in which the ordinates, while photo-electric currents, are proportional to the intensity of light emitted by the phosphorescing paint.

At the end of one hour the substance was just visible. Accurate measurements by the eye would have been practically impossible, whereas the electrometer was being deflected at a fairly measurable rate (over 0·1 mm./sec.); and this rate of deflection could have been increased many times had the exposed area of paint, and its distance from the cell been sufficiently altered.

When the data are plotted in the usual manner, with $I/\sqrt{I}$ against time the curve shown in Fig. 3 (II.) results. Except in a general way no great amount of importance should be attached to the compound linear character of this curve, as no special care was taken to eliminate or correct for the leakage currents mentioned in a previous article) through the glass walls of the cell, the object being simply to test the cell as a photometric device and not the study of phosphorescence.

Another possible application results from the fact that the total quantity of electricity discharged from the sensitive surface, and therefore the permanent deflection given to the electrometer, depends on the integral $I\,dt$, where I represents the light intensity over an interval of time dt. That is, such a combination of cell and electrometer is to light measurements what the electrolytic cell is to the measurement of quantity of electricity. In this way the study of short decay phosphorescence might be possible. The writer has also made measurements of the relative total quantity of light passing through a photographic shutter set at speeds of 0·01, 0·02 and 0·04 sec. For this purpose the closed shutter, mounted in front of the cell, was illuminated by a beam of parallel light. The "exposure" was then made and the resulting deflection of the electrometer noted. Unfortunately these data were not preserved and it must suffice to say that in the case of 0·01 sec. the deflection was 20 mm. or 30 mm.

Although possibly a little troublesome to work with, nevertheless it would seem that this phenomenon is capable of more extended laboratory use than has heretofore been made of it.

ELECTRICAL EQUIPMENT OF THE ROSE BRIDGE AND DOUGLAS BANK COLLIERIES, WIGAN.

BY W. WINSBOROUGH.

The Rose Bridge & Douglas Bank Colliery Co. first considered the electrical equipment of their collieries some years ago, and the present electrical installation was commenced early in 1903. This possesses several features of interest, as will be seen from the following brief description of the plant. Particular attention may be called to the method of preventing leakage and the protection against shock.

The power station is 60 ft. by 32 ft., and is built of pressed brick, the inside walls being of white glazed brick. The floor is covered with cork linoleum.

Generating Plant.—This consists of two 200 kw. 40 cycle three-phase 550 volt Brown-Boveri generators, direct coupled to Belliss & Morcom 250 H.P. compound engines running at 400 revs. per min., with direct coupled exciters, supplying power down the mine and on the surface for haulage, pumping and lighting.

Switchboard.—The main switchboard (Fig. 1) is of white marble, and is 15 ft. long by 6½ ft. high, all live parts at a pressure of over 230 volts being at the back of the board. There are five panels; reading from right to left these control two generators, the surface motors, transformers and shaft cables.

The two generator panels are each fitted with a voltmeter and ammeter, triple-pole switch, synchronising lamps and rheostat.

The third panel contains two ammeters, two triple-pole switches (one for a surface motor and one as spare), also an automatic voltage regulator, which keeps the pressure within 10 volts on either side, and a leakage indicator. No. 4 panel is equipped with two ammeters, two triple-pole switches (one for transformers and one as spare), also three change-over switches from transformers to direct-current generators for lighting the screens; whilst on No. 5 panel are two ammeters, two triple-pole switches, two triple-pole oil-break circuit-breakers with overload trips on two phases for the shaft cables, and a patent "Winhey" detector for the protection of the whole of the underground electrical apparatus. Fitted over the switchboard is a synchroniser clock and wattmeter.

Shaft Cables.—The cables from the switchboard to the pit shaft are run in troughing filled with bitumen, and then laid in casing down the shaft. This casing is clamped to the bearers and taken in at each pit eye to the main distribution boxes. These cables are 37/13 S.W.G. bitumen insulated, and are unarmoured, their length being 726 yds.

From the pit eye distributing boxes the motors are supplied with current through three-core steel-taped armoured bitumen cables, which are run behind the bar legs along the intake roads. This provides a splendid protection against falls of roof, &c. The length of the three-core cables is 3,144 yds., and their sizes range from 7/20 up to 37/13 S.W.G.

Underground Plant.—This comprises two 80 H.P., four 50 H.P. and four 25 H.P. motors for haulage and two 15 H.P. and two 5 H.P. motors for pumping. The motors are all of the Brown-Boveri slip-ring type, and are situated in the intake air roads, an ammeter, main and reversing oil switches and liquid starter being provided for each motor.

Digitized by Google

The cables are run to cast-iron fuse boxes at each motor, and are then extended on through fuses to the next motor, which makes a very convenient arrangement for isolating and testing purposes.

The haulages (Fig. 2) are of the endless rope type, and the gears are provided with 4 ft. rope wheels and treble reduction gearing driven from the motor through Unica pinions. The haulage ropes are from 400 yds. to 2,340 yds. in length, and are of 1 in. steel wire, hauling from the level and up to gradients of 1 in 2½ at a speed of 1½ miles per hour.

There are 200 incandescent 16 c.p. lamps installed underground, supplied at 230 volts through 6 kw. single-phase transformers;

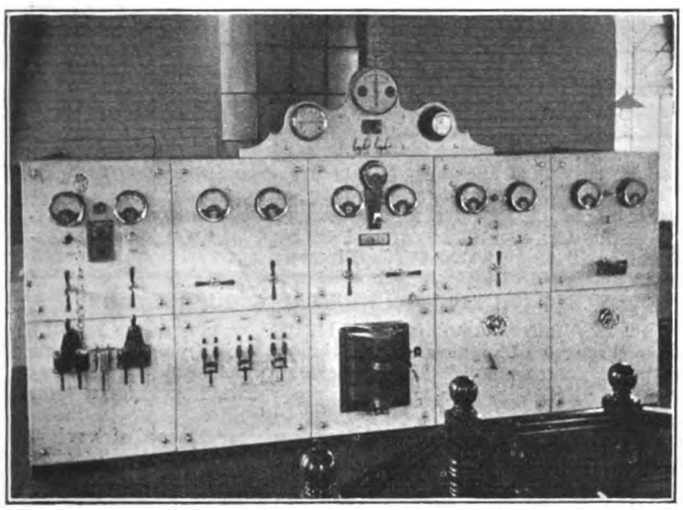

Fig. 1.—Main Switchboard.

whilst the whole of the mine signals are electrically operated, and each motor house is connected by telephone.

The patent "Winhey" detector mentioned above has been installed on the main switchboard for the past eight months, and has given every satisfaction. Although very sensitive, it has not caused the slightest delay in the working of the colliery. The object of the instrument is to cut off the current whenever a serious leakage occurs, or such leakage as would take place by a person accidentally touching a live conductor, and it thereby prevent any person receiving a severe shock, and obviates any fire risks through leakage.

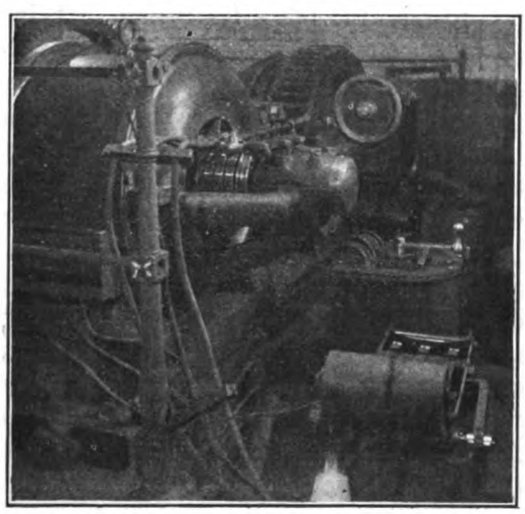

Fig. 2.—Electric Haulage.

The detector has been put through some very severe tests, and the spark obtained by putting one phase dead to earth is hardly perceivable. It has also been tested from all parts of the system with regard to the severity of a shock. In all cases the shock obtained was only very slight, owing to the quickness and sensitiveness of the instrument.

It has come into operation twice through punctures in the shaft cables caused through a blown-out steam joint. Considering that these cables are unarmoured and in wood casing, which practically insulates them from earth, it has well proved its value as a protection. This leakage detector has been a source of considerable interest to the numerous engineers who have visited this plant, and many have tested the same by making actual contact with a live conductor to prove that the detector will come into action with so small a leak as will pass through the finger tips without giving a severe shock.

Surface Plant.—The surface installation comprises one 25 H.P. motor for driving a dirt haulage and full tub creeper, one 2 H.P. motor for driving oil pumps, drilling machine and lathe for the lamp rooms, and one 1 H.P. motor driving a lamp cleaning machine.

There are 40 Crompton enclosed arc lamps for the sidings and workshops, also 480 incandescent lamps, which are supplied by three 12 kw. single-phase transformers.

REPORT ON CENTRAL STATION ADVERTISING.*

The report of the committee of the National Electric Light Association on central station advertising gives the result of a series of inquiries made of member companies, and contains a number of reproductions of newspaper advertisements. Fifty out of 80 companies report that newspapers form the very best medium of advertising for the central station, the next most popular method being direct-by-mail advertising. A very general use is being made of electric signs in advertising the office location of the company, and also the business of the lighting and power company at various favourable locations in cities where they operate. The maintenance of display rooms and display-window lighting has also become very general, but the use of billboards is very slight. The street-car card is only used by those companies spending large sums of money each year on advertising as a whole, or by companies operating traction lines in connection with their electric light and power business. The committee find that companies expending large sums of money employ almost all of the well-known advertising methods, while a limited expenditure for advertising narrows itself to the newspapers, company bulletins, direct-by-mail literature and the use of various booklets, folders, inserts, &c., furnished the operating companies by manufacturers of electrical apparatus and supplies. It is stated that the yearly amount spent by different companies shows surprising variations. The committee state that an appropriation for advertising, exclusive of soliciting, could reasonably be from 1 per cent. to 2 per cent. of the gross revenue of the larger, and perhaps from 2 per cent. to 3 per cent. of the smaller companies.

DISCUSSION.

Mr. L. E. Gibbs, of Boston, said that the small company always had an advantage in that it was closer to its consumers. Advertising helped to bring the large company nearer to its consumers. Along with it all employés must be impressed with the necessity of loyalty and of putting the best foot forward. The effect of advertising might be neutralised inside of a company's office if the enthusiasm of the advertising man was not contagious and did not permeate the entire force. In Boston a certain appropriation of kilowatt-hours every year was made for advertising the furnishing of energy to electric signs for electric contractors. The name of the central station company was not necessarily mentioned in such advertising. He next referred to the difficulties of keeping close to consumers in handling a large district with central supply, as in Boston and its suburbs. As a result of the distances between the main office and the various distributing centres, his company was about to decentralise its business organisation and to establish offices in each territory. These would be business centres for that territory, carrying a stock of supplies and dealing with the public directly.

Mr. M. E. Bearsley, of St. Louis, told of the advertising campaign which the Union Electric Light & Power Co. was engaged in. One of the features brought out was that power could be obtained by a manufacturer anywhere in the city, and that he did not have to rent an old-style building with power as in former days. The company also advertised for "kicks." While many came in response to this invitation it was believed that it was a good thing. The company advertised in a number of different daily papers.

Mr. J. C. McQuiston, publicity manager of the Westinghouse Companies, said that from figures recently compiled it appeared that about 90 per cent. of the population of the country were not using electric service. In small towns in the West as high as 60 or 70 per cent. were using the service. In some Eastern cities the percentage was as low as four. His companies were now furnishing advertising copy free of cost to central stations desiring it. This copy was prepared by specialists and was available to the central station company at a much lower price than if prepared specially by each company.

Mr. P. S. Dodd, publicity director of the National Electric Lamp Association, Cleveland, told how the lamp manufacturers had gone into the trade papers in various industrial lines to advertise their products. He also had prepared campaigns of advertising for central station companies.

Mr. C. W. Lee urged members to use the advertising matter which had been prepared by manufacturing companies and which was available at a nominal cost.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free,
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New volumes of "THE ELECTRICIAN" commence in April and October.
(This charge includes all Supplements.)
Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett. [Price 8s. 6d. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903). PROCEEDINGS AT.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-second issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for August 19.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

ELECTRICITY SUPPLY AS A BUSINESS.

During a discussion at the Institution of Electrical Engineers some two or three years ago the opinion was expressed by several station engineers that the introduction of the metal filament lamp would certainly temporarily, and perhaps permanently, affect their lighting loads. Some of those taking part even went so far as to say that the only way of preventing any reduction in revenue, due to this cause, was to raise the prices for energy—not, it will be agreed, a very commercial proposition, or one which was likely to appeal with any great force to their consumers.

The prognostications of these prophets of evil have to some extent been realised; and as all disaster is popularly supposed to be directly due to our own shortcomings, an immediate examination to discover whether anything was lacking in the economic conduct of our electricity supply undertakings was not out of place.

It did not take long to discover a point of weakness. The sense of stability of our electricity undertakings up to that time was too liable to engender in the staff, after the first few years of working, an inclination towards *laisser-aller* which is met with in most Government and many municipal offices. As long as it was possible to run the station fairly economically and to increase the number of consumers by an adequate amount each year, every one was satisfied and matters went quite smoothly. But the introduction of the metal filament lamp changed all this, and we are of the opinion that this invention has been distinctly a blessing to electrical engineering generally. Perhaps supply engineers may have thought that during the past two years the benefits have been rather disguised, but they, too, are now beginning to recognise that their troubles were of the chastening variety. The metal filament lamp has, in fact,

Digitized by Google

jerked many a supply undertaking into vigorous life, and the reduction in load has set many an engineer on a career of business-getting.

Now, this operation of business-getting can be performed in a number of ways. We are heartily in agreement, as regards principle, with the enterprise exhibited by those supply engineers who have set up show rooms and sent canvassers on travels round their area, but we have also had occasion to point out that much of this work has been undertaken without a clear idea as to the end in view, and that an inefficiency exists which an engineer should abhor, as we are told Nature abhors a vacuum. The responsibility of this publicity campaign has been placed in many cases on an engineering assistant. But it seems to have been forgotten that because a man is both a theoretical and practical expert in electrical engineering, and is well acquainted with the way in which a station should be run, it does not follow that he is also capable of persuading that shy bird—the prospective consumer—of the benefits which will result from connection to the supply mains.

A canvasser, no less than a poet, is born, not made. He must be possessed of brazen cheek and of the wisdom of the serpent, without the harmlessness of the dove. He must be able to treat his superiors, inferiors and equals in just the way in which they like to be treated, and in just that way which will eventually draw them on to the electricity network. He must be at home in other people's houses (a difficult accomplishment to many), and must be as capable of congratulating the lady of the house on the appearance of the baby, as the master of the house on his acumen in getting the better of the plumber. It will, therefore, be seen that the canvasser requires very different characteristics from those of the engineer, and that to employ one of the electrical staff on such work is a grave tactical error. No one would think of placing a whilom canvasser in charge of a generating station, though the reverse operation is apparently to many quite without its ridiculous side.

In Sunderland Mr. A. S. BLACKMAN has reached the stage of finding that canvassing cannot be efficiently performed by an engineering staff who are at the same time engaged on other duties; and he recently recommended that a canvasser be appointed to deal with this portion of the work. The reasons which have led him to this decision are not without interest. The number of units sold for lighting has, for the last two years, been decreasing, and the last of this decrease has, it is thought, not yet been reached; also the reduced cost of lighting, due to the new lamp, is not great enough to attract sufficient new consumers to maintain the former position. The new lamp, if it is to be used to the best advantage, requires the remodeling of installations to some extent, and thus "there is always a risk of losing consumers to an active opposition." This recognition of an "active opposition" is a confession of present weakness, which Mr. BLACKMAN should counteract by setting up a well-organised publicity campaign.

This, in fact, he proposes to do. Up to the present, canvassing has been conducted by the engineering staff, on commission, and in addition to their other duties. The scheme has not been a success, for as a result only 27 consumers have been added to the mains during the greater part of the year. Mr. BLACKMAN now points out the necessity for an up-to-date show-room to which prospective consumers may be invited. Further, he recommends the appointment of a canvasser, as he recognises that the work of obtaining new consumers cannot be carried out satisfactorily by the engineering staff. This is a step in the right direction. We are a little doubtful, however, whether the salary suggested—£78 and commission—is as high as it should be, and whether Mr. BLACKMAN will get a man of sufficient ability for the sum proposed to affect materially the number of new consumers. Even a canvasser is worthy of his hire, and the results obtained in such cases generally vary as the nth power of the salary given, the value of n being greater than unity, within certain limits. The question as to who should ultimately rule the electricity supply undertaking, the business manager or the engineer, is a wide subject which cannot be argued here, but it must be remembered that such undertakings are now business concerns and must, therefore, be carried on under commercial control, whether this control is subordinated to engineering requirements or not. This recognition at Sunderland of what is required is a hopeful sign, and we only trust that Mr. BLACKMAN'S example will be followed by many of his brother engineers.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Handbuch der Elektrotechnik. Vol. IX. "Elektromotoren, Umformer und Elektrische Motorantriebe." By Dr. F. Niethammer. 2nd edition. (Leipzig: S. Hirzel.) Pp. xvi. + 469. M.20.

This is a most difficult book to criticise. It is one of the most extraordinary conglomerations of electrical matter that it would be possible to imagine. Probably the best description of the book would be to call it a mixture of catalogues and text-books, but we only give this description for want of a better. The reviewer is at a loss what to do. To praise the book would be flattery, to condemn it would be unjust. But if we really must come to a decision, we might appeal to the analogy of a well-known allegory, and say that "parts of it are excellent."

The chief obstacle that prevents our making a satisfactory review of the book is that we cannot find out for whom it is written. We have tried all manner of heads, but the hat will not stay on any one of them. At times we think the book is written for the manufacturer, and go merrily on seeking what may be of interest to those engaged in this branch of electrical engineering. But, alas! we soon come to grief, for we find that in the descriptions of the machines—which occupy a considerable portion of the book—most of the examples given are reproduced from the 1900 edition; but this is 1910, and machines are being remodelled year by year. Moreover, the information given is seldom sufficient; usually it is indescribably meagre and scrappy, being apparently thrown together anyhow, whilst some of the types given refer to firms long since unheard of, being either merged into larger concerns or obscurity.

Nor even after a closer inspection are we able to modify these first impressions—in fact, there are so many examples to confirm this view that it is difficult to know which to select. Thus, Figs. 73 and 74 are plates showing a ¾ H.P. to 1 H.P. motor by Helios—which we take to be a former firm in Cologne. Of this motor, we learn that it is totally enclosed, has but one pole

Digitized by Google

wound, and a few other mechanical details, along with the usual dimensions given in a catalogue. No mention is made of voltage, speed, weights, nor of any electrical particulars whatever. In another instance the number and size of the slots, the armature dimensions and the flux density in different parts of the circuit are given. Indeed, scarcely any two motors seem to be treated alike, and practically none are described fully.

Equally unsatisfactory is the result when an attempt is made to criticise the matter from an historical point of view. But a gleam of hope did certainly come when we tried to fit the hat on to the head of the more general engineer, who, having either no wish or chance of making investigations for himself, might appeal to such a book to find out the practical part of the technical knowledge contained in text-books and genuine trustworthy information gleaned from the multifarious matter contained in manufacturers' catalogues and advertisements. But, alas! we are again disappointed here, for the material is given in very much the same way as it would be found in its original sources. On the other hand, what a useful handbook it would have made if such an independent authority had collected and summarised such material, and, after pruning all superfluous and obsolete matter, given a good critical digest of the remainder. Such a treatise would be appreciated by everyone, because it would be useful to everyone. The manufacturer, on the one hand, would be pleased to have such a treatment, for it would show him how his apparatus and machines ought to be designed and constructed in the light of best modern practice, whilst, on the other hand, the user would have a work placed in his hands informing him what he had a right to expect and demand, at the same time giving him a clear insight into the method of working of the various machines, so that when called upon to make his selection he would have the advantage of an unbiassed judgment. In other words, such a book would serve the double purpose of keeping the designer up to his work and at the same time make the intelligent buyer and consultant largely independent of the partial advice offered by the various competitors. For example, think what aid such a work would be to the man actively engaged in the manufacture of electrical machines to be able to compare his experience with that gained by other manufacturers. Equally useful it would be to the man engaged outside manufacture, who requires to know, let us say, why and when commutating poles should be used and the advantages obtained therefrom, what reasonable speed regulation may be expected thereby, and so on. Or, again, when ought one to sacrifice price for efficiency? at what output ought an induction motor to work at its best advantage? and how ought such a machine to be rated with respect to overload capacity and power factor? It is only on some such lines as these that we think a book like the present could be properly written, and because it has fallen short of this standard we are bound to consider it in some ways a failure. Moreover, it is certain that unless a treatise on electrical engineering is written with some definite object, there is little chance of its success in the ever-increasing volume of English, German and American literature published nowadays.

Turning again to the contents of the book, it is with the first two parts that we have chiefly to find fault. Part I., dealing with electric motors, occupies some 230 pages, just one half of the book. We have already stated our main objections to the unsatisfactory method of treatment and the out-of-date material. Part II., dealing with converters, occupies some 28 pages. Really we cannot understand why converters should have a place in the title of the book, especially when 15 out of these 28 pages deal with stationary transformers. Our chief reason, therefore, for not recommending the first two parts of the book is because the subject matter is treated much better elsewhere.

The last part of the book, Part III., dealing with "Electric Motor Driving," is by far the best. This section occupies some 200 pages, and is much better arranged than either of the other sections. Though even here there are many signs of incompleteness, yet the author has, on the whole, done well in the collection, arrangement and criticism of his matter. Starting with the selection of motors and their various accessories, he passes on to the application of electric motors to all kinds of cranes, lifts, transporters, winches, haulage gears, pumps, &c. In another chapter he treats of electric driving of tools, rolling mills and the like, whilst finally he sketches out the equipment of factories and other installations where electric power is employed. In addition to the large amount of interesting matter given in this section, there is also much useful data which can be well employed in planning out projected installations. STANLEY P. SMITH.

L'Électricité dans les Mines. By E. J. BRUNSWICK. (Paris: Gauthier-Villars.) Pp. vii. + 255. 7fr.50.

Some four years ago a series of very interesting discussions on electric winding took place at the Institution of Electrical Engineers and its various local sections, and opinion was very divided as to whether electrical winding could be economically adopted in place of steam. Even now our Engish mine owners and mining engineers do not seem to be quite satisfied that the decrease in running expenses due to electric winding will compensate for the increased capital expenditure of an electric over a steam winding plant; with the result that, although electricity is largely employed in England in other branches of mining work, there are but few examples of electric winding engines in this country. On the Continent, however, electric winding has made great headway both in France and Germany, the results obtained being in the majority of cases quite satisfactory.

The book under notice is almost entirely devoted to electric winding, and should be valuable to the English mining engineer, since it will enable him to see what has actually been accomplished in this direction on the Continent. The author presented a report on the electrical equipment of mines to the Congrès International des Applications d'l'Electricité, held at Marseilles in 1908, and this book is the outcome of his work upon that report. It will be seen, then, that the author has had an excellent opportunity of becoming familiar with every aspect of the subject of the electrical equipment of mines.

The book is composed of 19 chapters, of which the first eight are devoted to a brief treatment of the various applications to which electricity has been put in mines—for lighting the mine, for driving pumps and ventilators, special motors for service at the bottom and for haulage and traction systems. The benefits to be derived from the application of electricity to all these purposes is now quite generally recognised, and already electrical power is being largely used in England for such work. The whole of these subjects are dismissed in less than 40 pages, the remainder of the book being given up to electric winding.

The advantages which electrically-driven winding gear possesses over steam winding machinery are all clearly stated; the author, too, states clearly the advantages claimed for the Koëpe pulley—so largely used on the Continent—over ordinary winding drums. English engineers, however, are in favour of winding drums. The various continuous and alternating current systems in use, and the methods of equalising the load on the central station are all discussed at some length, and an actual installation is worked out for the three most important systems at present in use. The remaining two-thirds of the book are devoted to actual detailed descriptions of the most important and typical installations at present in operation, and should prove very useful to mine managers and consulting engineers.

The book throughout is clearly and simply written; it is essentially a practical treatise, and should prove a good investment for all engineers connected with mining work, and also for students of mining engineering. A. E. C.

"The Gas, Petrol and Oil Engine."—Messrs. Longmans, Green & Co. write us that the published price of vol. I. of "The Gas, Petrol and Oil Engine," by Dugald Clerk, which was reviewed in our last issue (p. 777) is 12s. 6d. net, *not* 4s. 6d. net as erroneously stated.

AN OVERLAP LOOP TEST.

BY DANIEL SHIRT.

The loop method of fault localisation on electric mains has found favour with many engineers; yet there are still to be found those who fail to realise the great accuracy attainable by its means and who prefer one or other of the so-called "fall of potential methods."

Apart from the errors introduced in the latter methods by variations in the resistance of the fault and possible variations in the earth potentials at the fault and the testing point, produced by stray tramway or other currents, one may easily make an error of, say, 1 per cent. in reading the instrument deflections. This last source of error does not obtain, however, in "null" methods. Then again the instrument itself may have an index error of over 1 per cent. On the other hand, the accuracy of a loop test is only limited by the permissible strength of the testing current, and the sensibility of the galvanometer employed, provided due regard be given to the elimination of contact resistances.

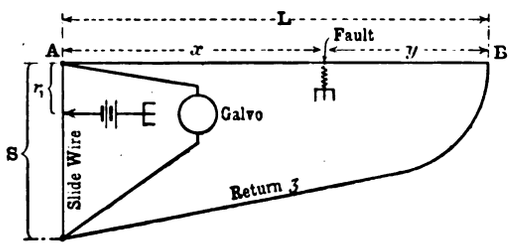

FIG. 1.

Mr. F. C. Raphael, in his excellent work "The Localisation of Faults in Electric Lighting and Power Mains," deals with the subject of loop testing in a comprehensive manner, and points out the few simple yet necessary precautions to be observed. In the present article the writer proposes to deal with a particular method of applying the Murray test, which possesses, he believes, distinct advantages.

Cases frequently occur in fault localisation by loop test where it is found necessary to employ a *return* of different section or length from that of the faulty cable. In such cases, failing exact data as to the ratio of the resistances of the two conductors, or the diameter and number of wires in each cable, one would be compelled to assume that their resistances were in inverse ratio to their *nominal* sectional areas. For example, a nominal 0·50 sq. in. cable would be assumed to be double the resistance of a nominal 1·00 sq. in. cable. The true ratio, however, between the resistances of these cables—assuming

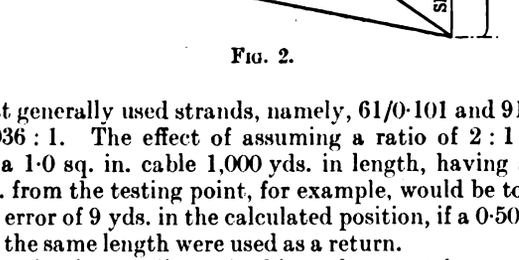

FIG. 2.

the most generally used strands, namely, 61/0·101 and 91/0·118—is 2·036 : 1. The effect of assuming a ratio of 2 : 1 in the case of a 1·0 sq. in. cable 1,000 yds. in length, having a fault 759 yds. from the testing point, for example, would be to introduce an error of 9 yds. in the calculated position, if a 0·50 sq. in. cable of the same length were used as a return.

By the simple expedient of taking a loop test from *each* end of a faulty cable, we need not know the resistance of the return, or even of the line, if it does not vary in section, provided the resistance of the loop remain constant.

Further, leakages to earth from the return itself become partially compensated for, because the calculated position of the fault will always lie between the two resultant faults due to such leakages.

Let AB (Fig. 1) represent a faulty cable of constant section and resistance L, divided by a fault into two sections x and y. Let us call the resistance of the return z. Let us also assume that a slide-wire bridge is used to carry out a Murray loop test at each end. At the end A, balance will obtain when the slide-wire is divided into two portions, such that $r_1 : S :: x : x+y+z$. Similarly, at the end B (Fig. 2), balance will obtain when $r_2 : S :: y : x+y+z$. Compounding these ratios

$$r_1 : r_1+r_2 :: x : L.$$

That is,
$$x = \frac{r_1 L}{r_1+r_2} \quad \ldots\ldots\ldots \quad (1)$$

Obviously, this equation is also true if we express x and L in units of length (yards, for instance), and r_1 r_2 in number of divisions of slide-wire from the points A and B, respectively.

It will be noticed that neither the resistance of the return nor the total length of slide-wire enters into this equation. It is, therefore, clear that when the resistance of the return is high compared with that of the faulty cable, we may, by adding a resistance in series with the slide-wire, increase the values for r_1 and r_2, which might otherwise be too small to read to the required degree of accuracy. This added resistance must not, of course, be altered throughout the tests, and should, if possible, be of the same metal as the slide-wire itself, otherwise errors may be introduced by possible differences in temperature at the testing points.

This test, with a simple correction, may often be advantageously employed in fault localisation on multicore or concentric cables, where a sound return is not available, but, in this case it is necessary to know the ratio between the resistances of the line and return conductors, where great accuracy is desired. A typical case of this kind would be where a fault had developed on one conductor of, say, a three-core cable, and that the insulation of the other conductors had fallen considerably owing to the ingress of water or the development of excessive heat at the fault.

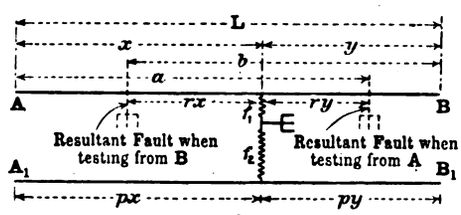

FIG. 3.

Fig. 3 illustrates diagrammatically a case of this kind, only the two conductors used for the test being shown.

Let f_1 and f_2 be the fault resistances of the conductors AB and A_1B_1 respectively, f_2 being high as compared with the resistance of the loop.

Let $x+y=L$=the resistance of AB.

Let $p(x+y)$=the resistance of A_1B_1, where p is the ratio of the resistance of A_1B_1 to that of AB.

Let a=the resistance from A to the resultant of the faults f_1f_2, as found by test from A, BB_1 being coupled together.

Let b=the resistance from B to the resultant of the faults f_1f_2, as found by test from B, AA_1 being coupled together.

Let $r = \frac{f_1}{f_1+f_2}(1+p)$.

Then, $x=a-ry$ and $y=b-rx$. From these equations we obtain

$$x = \frac{(a-br)\,L}{(a+b)\,(1-r)} \quad \ldots\ldots\ldots \quad (2)$$

As in equation (1) we may express x and L in units of length, and a and b in the number of slide-wire divisions from the points A and B to their respective points of balance.

Referring to Fig. 3, we see that the distance between the resultant faults is rL. Therefore, if by P we represent that length of slide-wire which corresponds to the conductor AB, namely, $\frac{S}{1+p}$,

$$r = \frac{a+b-P}{P} \quad \ldots\ldots\ldots \quad (3)$$

Digitized by Google

Note that the value of x is indeterminate when $r=1$, that is, when $a=b=P$, and that the smaller r becomes, the nearer x approaches to the value $\frac{aL}{a+b}$.

Let us now consider a numerical example. A fault occurs on, say, a three-core cable 1 mile in length, having cores nominally of equal section. Selecting for our line and return the two cores having the lowest and the highest resistances to earth respectively (a few cells and a linesman's detector are convenient for this purpose), we carry out a Murray test, first at the end A and then at the end B. Let us assume that we obtain 247 and 278 divisions for our balance points respectively. We, of course, are careful to measure our slide-wire divisions from the *same* core at each end. Let us further assume that our slide-wire has 1,000 divisions (in practice one must allow for the effect of connecting leads when their resistances are not negligible quantities). Now, the number of slide-wire divisions corresponding to our line conductor is in this case $\frac{1,000}{1+1}=500$. Substituting for a, b and P in (3),

$$r=\frac{247+278-500}{500}=\frac{1}{20}.$$

Again, substituting in (2)

$$x=\frac{\left(247-\frac{278}{20}\right)1,760}{(247+278)\left(1-\frac{1}{20}\right)}=822{\cdot}6 \text{ approx.}$$

We therefore search for the fault 822·6 yds. from the end A.

As a check on the accuracy of our figures, we may calculate the result by reading the number of slide-wire divisions to the points of balance from the *other* core at each end. At the end A we have 1,000−247=753 divisions, and at the end B we have 1,000−278=722 divisions.

In this case

$$r=\frac{753+722-500}{500}=\frac{39}{20}.$$

Substituting in (2), we obtain as before

$$x=\frac{\left(753-722\times\frac{39}{20}\right)1,760}{(753+722)\left(1-\frac{39}{20}\right)}=822{\cdot}6.$$

In the example we have just considered, it will be interesting to investigate the effect of making an erroneous assumption as to the relative resistances of our line and return. Let us suppose that the return is 2 per cent. higher than the line. (This is a very much greater percentage than is likely to obtain in modern multicore cables.) Now, the number of slide-wire divisions corresponding to the line in this case is $\frac{1,000}{1+1{\cdot}02}$ =495 approx.

Consequently

$$r=\frac{247+278-495}{495}=\frac{2}{33},$$

and substituting in (2)

$$x=\frac{\left(247-278\times\frac{2}{33}\right)1,760}{(247+278)\left(1-\frac{2}{33}\right)}=821{\cdot}3 \text{ approx.}$$

From this result we may conclude that one is not likely to be misled to any great extent in multicores of nominally equal section, if they do not exceed a mile in length.

In order to apply the above formulæ when using a box of resistance coils, r_1, r_2, a and b must represent ratios obtained in the usual manner, namely, the ratio of the resistance in the arm adjacent to the core from which one wishes to obtain one's readings, to the total resistance unplugged in the box. P will then be $\frac{1}{1+p}$, *i.e.*, the ratio of the resistance of the line to that of the loop.

With regard to the relative merits of the two kinds of bridges, it would appear that the slide-wire is to be preferred to the resistance box for fault localisation on low resistance loops, because a reading to the third, or even the fourth significant figure can be readily obtained, notwithstanding that the wire may have a resistance of ½ ohm, or even less. On the other hand, with the usual types of resistance boxes, to obtain a ratio to the third significant figure, one has usually to unplug more than 100 ohms. This is a decided disadvantage in most cases. Plug contact resistances, too, often introduce serious errors. Moreover, a current which would seriously overheat the coils of a resistance box, and thus prejudice the accuracy of a test, could be passed through an ordinary slide-wire bridge with impunity.

Where two faults are known to exist, as in cases like the numerical example given above, the testing current must be reduced as much as the sensibility of the galvanometer will permit; otherwise r may vary slightly during the test. It will generally be found better to balance to "false zero" when a third core is available through which the galvanometer may be earthed at the fault itself. The testing current may then be reduced to a minimum.

Where the galvanometer "kick," due to the difference in the capacities of the line and return, is troublesome, it may be eliminated by inserting a suitable variable condenser, or a standard condenser with a variable series resistance between the line terminal of the bridge and the galvanometer earth.

ABNORMAL TRANSMISSION OF ELECTROMAGNETIC WAVES.*

BY PAUL SCHWARZHAUPT.

It is well known that wireless telegraph stations whose normal range is, say, 100 km., may, under certain conditions, be heard at a distance of 1,000 km. or more. The Table on next page gives examples in which a reciprocal intercourse was possible between the stations named.

The ships named have a range of 300 km. to 500 km.; that of Scheveningen and New Orleans is about 700 km.

From the table it appears that the phenomenon of abnormal range only occurs at night. This is probably due to the low ionisation of the atmosphere after sunset. Towards sunrise the distance that can be reached takes its normal value.

Frequently one station may be heard by another at a great distance away, but not the second by the first. On Dec. 17, 1908, evening, the ss. "König Wilhelm II." and "Cap Roca" communicated with one another over a distance of about 50 miles, south of Lisbon. At the same time the ss. "Cap Arcona," in the English Channel, heard, during several hours, the correspondence of both ships, at a distance of 2,400 km. On Oct. 17, 1908, the "Bremen" was able to receive telegrams from the Norddeich station, near Bremerhafen, at midnight, in the harbour of Port Said; the distance being about 3,100 km., one-third over sea, two-thirds over land.

On Jan. 14, 1909, in the evening, the "Bremen," when north of Haaks lightship, in the North Sea, heard distinctly not only the two stations at Marseilles but also the signals between the American warship, going from Port Said to Marseilles, and Algiers.

It is strange that such favourable results have only been obtained at quite definite places, such as the Gulf of Lyons, Port Said, the region between Cape Finistere and Lisbon; a place in the Atlantic Ocean, long. 10° 15′ W., lat. 48° 40′ N.; the neighbourhood of Scheveningen and Haaks lightship.

An interesting series of observations was made on the s.s. "Bremen," during a voyage in the Mediterranean Sea, whilst receiving from the Norddeich station over the Alps. When leaving Naples, about 540 km. south of Genoa, telegrams could be received at night, with an intensity which we will denote by unity, next day 260 km. south of Genoa, the intensity had decreased to 0·65, rising at night in the harbour of Genoa to 2·4, and falling next day at the same place to 0·085. Thus, although the intensity in the daytime decreased as the ship approached the Alps, no such effect was observed at night.

The variation in intensity for the whole journey is shown by the curves. The ordinates, which represent the intensity, are the ratios of the resistance of the telephone to that of a shunt across it;

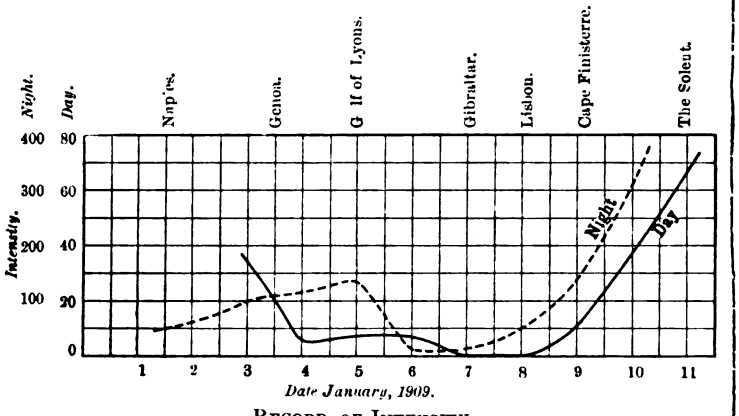
the latter being adjusted each time so that the signals could just be distinguished. The deep depression on the curves corresponds to the time of passing the Spanish mountains, illustrating the powerful deflecting or absorbing effect of mountains and forests. It may be noticed that the intensity at night was always sufficient to allow the telegrams to be received. At the place on the curves corresponding to the Gulf of Lyons there is a distinct maximum. Here it was found possible to signal to Scheveningen, a distance of



RECORD OF INTENSITY.

1,200 km., and it is striking that this favourable direction follows that of the Rhone Valley. It is also noteworthy that the Ushant station heard these signals of the "Bremen," this direction coinciding with that of the Garonne.

With regard to atmospheric disturbances, the following observations have been made:—

1. The disturbances always begin in the afternoon, reaching their maximum towards midnight, and disappearing almost completely by sunrise.
2. They are most frequent in tropical climates.
3. They are more violent in summer than in winter, in consequence of the more frequent thunderstorms.
4. They are particularly noticeable in the neighbourhood of high mountains, *e.g.*, the Red Sea, the coasts of Italy and Spain. In the Mediterranean Sea the disturbances in winter are relatively weak.

Frequently violent disturbances are observed when the sky is quite clear; it is assumed that these proceed from a distant thunderstorm.

Unfortunately, little has so far been published on this subject. It is desirable that reliable statistics should be collected and radio-topographical maps prepared, which would be particularly useful on ships equipped with radio-telegraphic apparatus.

CORRESPONDENCE.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice from a cutting from THE ELECTRICIAN sent on to me here that Mr. Hookham points out that no one has taken up his challenge. I did not do so in detail myself as I was just leaving for this part of the world, but if you will grant me the space when I return I shall be glad to make the attempt to show that exports do not pay for imports.—Yours, &c.,

Calgary, Alberta, Aug. 4. A. BRUCE ANDERSON.

THEORY OF THE QUADRANT ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The method of establishing an electrometer formula adopted by Prof. Robertson, in his letter in your issue of August 19th, is the familiar and traditional one based on a consideration of changes of capacity in the system. In my article, purposely and avowedly eschewing this method, I base everything on a consideration of the electrostatic forces at work. It may be a retrograde step to call a force a force, rather than a space rate of change of energy, but it certainly seems to me that by doing so there is a distinct gain in clearness of treatment and simplicity of statement when dealing with certain classes of electrometer problems.

The final formula arrived at by Prof. Robertson looks curiously odd with V_1 absent from the denominator on the right-hand side, which would seem to suggest a mistake somewhere. In working with the method used by him, I have been in the habit of assuming that, for small deflections and with initial symmetry, $dc_1/d\theta$ and $dc_2/d\theta$ are linear functions of θ and can be represented by $a-b\theta$ and $a+b\theta$ respectively. This is equivalent to assuming that the electrostatic forces on the two sides of the needle vary linearly, and is more general than the assumption of Maxwell that the capacities on the two sides vary linearly. The formula then becomes

$$\theta=\frac{a(V_2-V_1)\left(V-\frac{V_1+V_2}{2}\right)}{k+\frac{b}{2}(V-V_1)^2+\frac{b}{2}(V-V_2)^2};$$

but this can hardly be regarded as more than a special case of the electrometer formula. In an actual electrometer, one can readily see, on general principles, that a term containing the product V_1V_2 may be required in the denominator, as in the last formula in my Paper quoted from Orlich's "Elektrometrische Untersuchungen." Clearly Prof. Robertson's original equations, when correctly worked out, lead to the formula just given, $\frac{1}{2}\left(\frac{dc_1}{d\theta}+\frac{dc_2}{d\theta}\right)$ being written for a, and $\frac{1}{2\theta}\left(\frac{dc_2}{d\theta}-\frac{dc_1}{d\theta}\right)$ for b.

My definition of the electrostatic controlling couple was made with reference to an electrometer in which the deflection θ is small, and in which the needle is subject to a mechanical controlling couple proportional to the deflection. If in such an electrometer, the total electrostatic couple can be represented by the first two terms of a series $A+B\theta+C\theta^2$ &c., then it is quite right to call the term A the deflecting couple and the term $B\theta$ the electrostatic controlling couple. Obviously A and B will in general be functions of all the potentials concerned, and the electrostatic control will, therefore, depend upon the potentials V_1, V_2 of the quadrants as well as on the potential V of the needle. But in the ordinary use of the electrometer to measure small P.D.s the needle is charged to a potential V, high relatively to V_1 and V_2, and A is proportional to $V(V_1-V_2)$, whilst B is proportional to V^2, being thus independent of the quadrant potentials. To these assumptions I see nothing either unjustifiable or unusual; but, of course, any attempt to apply the term electrostatic control,

Digitized by Google

in the above sense, to cases not contemplated in the definition, may easily turn out to be both the one and the other.

The notion of an electrostatic control, defined substantially as I have defined it, dates back many years, as Prof. Robertson will find on consulting the literature of the subject. Strangely enough, it has not yet filtered down to the common English text book.—I am, &c.,

Manchester University, Aug. 20. ROBERT BEATTIE.

STREET LIGHTING IN WESTMINSTER.

In our "Editorial Notes" last week we drew attention to the way in which the Gas Light & Coke Company was advertising its success in retaining certain portions of the street lighting in Westminster. From the paragraphs published on the subject it appeared that electric lighting was to be quite ousted from the city, and this because of the much greater cheapness of gas. We pointed out that the case for electric lighting was most unfairly stated, and that the true reason for the wide difference in the tenders for the two illuminants was due to the fact that the gas company were quoting an unprofitable price, in the hope that advertisement would ensue. This point of view is upheld in a letter which we have received from the Charing Cross, West End & City Electricity Supply Co. giving an extended statement of figures on the subject. We are glad to see that this statement is finding its way into the daily Press, with the result, we hope, of counteracting to some extent the value of the gas company's recent and future advertisements. This letter also brings out very clearly the disabilities under which the electric light companies suffered as regards the time limit for the repayment of capital, and from which the gas companies are free. The question as to whether the electric light companies were pursuing a proper policy in dealing with the necessary capital charges as they did has already been dealt with by us,* though we agree with our correspondent that the conditions of the specifications might have been made more flexible than was actually the case. The letter is as follows :—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is being persistently reported in the public Press that the City of Westminster have displaced electricity by gas for street lighting throughout that city. This statement, however, is untrue. The facts are as follows :—

The Westminster City Council transferred the lighting of that part only of the City of Westminster which has been hitherto very efficiently and economically lit by the St. James's Electric Light Co. to the gas company. This lighting comprised the supply to 66 arc lamps. The Westminster Electric Lighting Co. under contract are still supplying, and will continue to supply until 1931, 970 arc lamps, and the Charing Cross Co., under contracts which do not expire for some years, 165 arc lamps in the City of Westminster. It will be seen therefore that about 5¾ per cent. only of the lighting previously carried out by the electricity supply companies has been entrusted to the gas company.

These figures speak for themselves, and need no further comment on this head. When, however, so much attention is being called to the difference in the price quoted by the electricity supply companies and the gas company respectively, it is only fair to the former that the conditions under which the respective prices were quoted should be understood and appreciated, and I therefore call attention to the following points :—

The electric supply companies were invited, at considerable capital cost, to enter into a contract for five years, determinable at the expiration of that period at the option of the City of Westminster without compensation of any kind. Prices were also invited alternatively for 10 and 15 years contracts.

By the terms of the specification, the electricity supply companies (the gas company's network of street lighting mains already covered the entire area) were compelled to quote for the *whole* of such specific district or districts as might be within their particular area of supply. The City of Westminster Council on their part reserved the right *to select any part or parts* of those districts for lighting by electricity to the exclusion of other parts of the district, at the contract price per lamp quoted for the whole district. It is obvious, therefore, that the electricity companies in the event of the exclusion of parts of the district, might suffer serious loss.

The concessions of the electricity supply companies expire in 21 years and all capital charges would have to be provided for within that period. The gas company is not purchasable by the local authority, and has, therefore, a practically unlimited period in which it would be possible to deal with capital charges.

The furnishing of the supply by the electric light companies would have necessitated the laying of additional cables and the construction of other works involving a very large capital expenditure. With the gas company, as to the greater portion of the work involved, mains were already laid and capital expenditure made.

The terms of the specification imposed by the Westminster Council were thus (unintentionally, no doubt) exceedingly unfair to the electric lighting companies, and, owing to existing conditions, were relatively favourable to the gas company.

In circumstances such as these, could the electric light companies do otherwise, on business lines, than safeguard their shareholders' interest by making provision for these capital charges and contingencies in the price quoted per lamp? What could have been done if the specification had been framed so as to allow the companies, as well as the City of Westminster, to select convenient portions of districts for tender, is evidenced by the fact that the St. James's Company, owing to matters which transpired at the Westminster City Council meeting of April 14 last, offered to continue their supply to the section then lighted by them at a price which compared not unfavourably with the gas company's. Their request, although supported by nearly the whole of the principal shopkeepers in the area, was refused on the ground that it had already been decided to place the contract with the gas company.

It has also been published abroad that the City of Westminster will effect very large savings by the arrangement with the gas company. This is not accurate *qua* electric lighting. The City of Westminster in this connection is saving only the small difference between the low price charged by the St. James's Co. and the cut prices offered by the gas company. If, therefore, a saving is being effected, it is probably due to the drastic revision of the gas company's own prices for the supply they themselves have hitherto given in the City of Westminster.

The question whether or no the contract will pay the gas company other than as an advertisement is, of course, one for themselves and their shareholders, but an analysis of their published accounts would appear to show that their costs are 1s. 10d. per 1,000 ft., while the contract price, which includes capital charges for street work, would appear to yield certainly not more than 10½d. per 1,000 ft. as against 2s. 8d. per 1,000 ft. charged to the general public. Would it be very unfair to deduce that considerations of advertisement and preference had an undue bearing upon the composition of the prices tendered by the gas company?

To put the matter shortly, making allowance for the considerations mentioned in the preceding paragraph, the whole of the difference between the price tendered by the gas company and the electric lighting companies respectively is due to this question of capital charges in connection with the short unexpired periods of the provisional orders, the duration of the proposed contract (five years) and the handicapping conditions imposed by the terms of the tender upon the electricity supply companies, and not in the price at which electricity could be sold under ordinary and reasonable conditions.—I am, &c.,

EDWD. WILLMOT SEALE, Secretary.
The Charing Cross, West End & City
London, W.C., August 20. Electricity Supply Co. (Ltd.)

The method of arriving at the above figures of 1s. 10d. per 1,000 cubic ft. (the cost to the gas company of the gas sold to the public at 2s. 8d. per 1,000 cubic ft.) and 10½d. per 1,000 cubic ft. (the price likely to be obtained by the company under their contract with the City of Westminster) is set out by Mr. Seale in a further communication. The substance of this is as follows :—

High Pressure Gas.—According to Mr. Bradley's report published in THE ELECTRICIAN of March 11, 1910, a 1,000 c.p. (nominal) high pressure gas lamp, giving an average candle power of 880, takes 30 cubic ft. of gas per hour; therefore a 3,000 c.p. lamp must take at least 90 cubic ft., or, say, 1,000 cubic ft. per 11 hours. As the number of lighting hours per annum are 3,940, the total consumption of gas would therefore be 354,600 cubic ft.

With gas at 10½d. per 1,000 cubic ft. the cost of 354,600 ft. is	£15	10	3
Leaving for maintenance of 3,000 c.p. lamps (3 mantles)	6	9	9
Contract price	£22	0	0

It should be noted that maintenance items are not chargeable against private consumers in the price of 2s. 8d. per 1,000 ft., so this item is therefore omitted in the comparison, and the figure of 10½d. compares with 2s. 8d. Also, when the extreme urgency of the conditions relating to maintenance of candle-power for the street lamps is borne in mind, it will be evident that the above sum allowed for maintenance will probably be exceeded.

Moreover, no allowance has been made for capital charges. In this connection, it is true that the expenditure has already been incurred in the greater part of the area, but we understand that special mains are being laid for the 3,000 c.p. lamps, so that the figure of 10½d. must include capital charges, and make the price more inadequate still.

In regard to the cost of manufacturing the gas, the following figures

* THE ELECTRICIAN, Vol. LXV., p. 92.

Digitized by Google

are taken from the half-yearly accounts, to December 31, 1909, of the Gas Light & Coke Co. :—

		1,000 cubic ft.
Gas sold by meter		10,846,734
Gas sold, public and contracts		445,772
Gas manufactured		12,109,500
Costs.		
Total costs, including distribution		£1,424,941
Less lighting and repairs of public lamps	£19,573	
„ depreciation of works on leasehold lands	500	
„ received for residuals	367,517	
		387,590
		£1,037,351

The cost per 1,000 cubic ft. of gas manufactured is therefore 1s. 8½d., and cost per 1,000 cubic ft. of gas sold 1s. 10d.

UNDERGROUND WINDING PLANT OF THE NEW MODDERFONTEIN G.M. CO.*

BY R. H. COPELAND.

The object of these notes is simply to show difficulties contended with in installing the cable, getting the hoist into position, and to describe and show the system of control, safety devices, &c. The winding plant referred to is of a somewhat unique type, being the largest ever erected on the relay contact system. It is not submitted that this is the ideal system of hoisting, but a description of it will no doubt be of interest. The hoist was under order from the manufacturers some considerable time before a decision was arrived at by the management to instal the three-phase system for the electrifictaion of the remainder of the mine. I do not anticipate that another hoist of this particular type will be erected on these fields, owing to the cost of cable, &c., unless it is in close proximity to a local power station.

The plant was installed for the purpose of hauling in the incline shaft, which necessitated cables being laid from the power house to the collar of the shaft, a distance of 200 ft., down the No. 1 shaft vertically 280 ft., and on the incline (40 deg.) 1,220 ft., then 840 ft. through a crosscut, along a drive for 340 ft., and up a slope to the hoist chamber 220 ft., a total length of 3,100 ft. Before commencing this work, a temporary telephone system was put in, which proved an invaluable acquisition.

Two cables were laid, a positive and negative, having a total length of 6,200 ft., and a weight of 50 tons. The cable, composed of 61 wires between Nos. 8 and 9 S.W.G. of a sectional area 0·9 sq. in., insulated with impregnated paper, 0·50 in. thick, on which was laid one layer of very thin linen tape, lead covered, armoured with flat steel wires and served. The overall dimensions were 2 in. The lowering of the cable was effected by means of a disused hauling engine drum with good brakes. The cable drum was mounted on trestles and three turns taken round the engine drum. As soon as one cable drum was emptied, each successive length of cable was clamped securely with four clamps to the end of the previous cable and lowered down the shaft. Rollers were fixed every 30 ft. through the cross-cut, a very winding passage, necessitating many vertical rollers at the bends. The cable was rolled through to the mouth of the drive, after which natives were employed to carry it to the stope. 650 hardwood clamps were used in fixing the cable to the timbers, cross-arms, &c. The cable was moving the whole distance from the engine drum, down the shaft, through the cross-cut, and along the drive to the foot of the stope at the same time ; the only accumulation of cable which could be allowed was a large bend at the bottom of the shaft.

The jointing of the cable was effected with brass sleeves 6 in. long by $1\frac{5}{8}$ in. internal diameter, with two rows of set screws holding the ends of the cable firmly in the sleeve while the joint was being soldered. The joint was finally placed in the usual cast-iron junction box and filled in with bituminous compound. There were 10 junction boxes installed. The insulation of this paper cable required very careful treatment. In one instance a piece was cut off the end of the cable in a moist atmosphere underground and tested, showing 40 megohms ; the end was exposed for about an hour and then securely sealed. The following day the same length was tested, and gave 1½ megohms. A further length of 6 ft. was then cut off and tested, 40 megohms being again shown ; this illustrates the hygroscopic character of paper insulation in general, and of this cable in particular. After this, and several other similar experiences, it was found necessary to make the joints as quickly as possible.

* Abstract of a Paper read before the South African Institute of Electrical Engineers

The mechanical engineering department experienced quite an anxious time in lowering the hoist parts underground (a different route was taken from the one used for the cable). The cases, &c., were lowered down No. 2 shaft (vertical, 1,200 ft.) during week-ends ; they were stacked in every available nook along the mechanical haulage way, weeks prior to their being required for erection. The hoist chamber is situated about 200 ft. up the stope, which is about 4 ft. high and at an angle of 50 deg., and it contains the hoisting engine and motors, the contactors, controller, resistances and switchgear. All the material was taken up by a winch, the heaviest part weighing 5 tons, the longest, the shaft, being 18 ft. The total weight taken up amounted to 83 tons.

The winding drums are 8 ft. in diameter, and 5 ft. 6 in. wide, and are geared to two eight-pole compound wound motors, with auxiliary poles, coupled back to back in tandem. Each motor runs at 450 volts, and 364 revs. per min., and has a capacity of 210 B.H.P. for continuous operation, or 415 B.H.P. for three minutes. Two motors were considered preferable to one large motor, allowing the series parallel control to be used, and having the advantage of smaller armature diameters to reduce the flywheel effect. These motors are of the ventilated type, Morganite brushes being used, and up to full load the commutator is absolutely sparkless. The shunt field windings of both motors are connected in series, and in series with the brake magnet, and are constantly excited. It is a question whether the advantages derived through having shunt fields are sufficient to warrant expending 5 kw. continuously in their excitation.

The drums are fitted with hard wood brake blocks. Under normal working conditions the brakes are actuated by compressed air by means of the usual hand lever, but a drop weight serves as a safety brake, and is actuated through the depth indicating gear, or in case of the current being interrupted, by the magnetic brake. The drop weight is kept balanced by a compressed air cylinder, but it can also be released by the emergency hand lever.

The discharge resistance supplied for use in switching off the motor fields was discarded, and a bank of lamps, 16 c.p., 120 volts, four rows of 12 in series parallel, was installed, which took the back kick satisfactorily. As an extra precaution a carbon sparking gap set at $\frac{1}{32}$ in. was inserted.

On the main switch panel there is an automatic circuit-breaker, one double-pole main switch, one double-pole field switch with field discharge resistance, and volt and ampere meters. From this panel the cables are taken to the emergency apparatus panel, situated on the left-hand side of the foot-plate and easily accessible to the driver. The emergency panel consists of one circuit-breaker with no voltage release, brake magnet short-circuiting device, overwinding arrangement, and emergency press button switch. From thence the cables lead to the cast-iron instrument column (directly in front of the driver) carrying volt and ampere meters and air-pressure gauge, to guide the driver in starting up, and to indicate whether the correct air-pressure is available for the brakes. From the iron instrument column the wires go to the contactors.

The contactor cases, each weighing 600 lb., are mounted on a 3 in. angle iron frame, 24 ft. long by 10 ft. high, standing on a concrete foundation, and securely fixed by wedge bolts driven into the rock. The total weight of contactor cases is 6,000 lb. ; the weight of contactor bus-bars, 1½ in. × ¼ in. copper (five sets), is 150 lb. The contactors, 46 in number, are contained in 10 iron cases. There are three copper movable contacts on each contactor dealing with the main working current. The central contact is set slightly in advance of the outer two, which causes it to make contact first and break contact last, taking the full effect of the flash. This contact is easily changeable, although I consider a carbon break might have been used here to advantage.

The controller is of the horizontal drum type with 18 in. diameter drum and 32 finger contacts. It is actuated by the starting lever. The lever is set up for the driver in precisely the same way as in the case of a steam winding engine. In the mid position of the lever, the current is cut off and the motors electrically disconnected ; on moving the lever backwards or forwards the current is sent through the armatures and auxiliary poles of the motors for one direction or the other of rotation. There is an arrangement of dash pots on the controller which prevents the driver from throwing over the lever too quickly, allowing only a step by step action, but the lever can be brought back to the mid position instantly. The current dealt with by the controller is very small, so that sparking at controller contacts is negligible, and a blow-out quite unnecessary. The resistances are of the cast metal grid type, and are contained in four perforated metal cases. The series parallel control is used.

Should the driver at any time lose his presence of mind, the various safety devices are : (1) The electrical overwinding gear, a form of knife switch actuated by the depth indicating gear. Its action is

Digitized by Google

to short-circuit the no voltage coil, releasing the circuit-breaker, which also short-circuits the brake magnet, cutting off the compressed air supply, and putting on both brakes. (2) The press-button switch acts in an exactly similar manner. (3) There is a small emergency lever adjoining the control lever, the throwing over of which releases the drop weight, cutting off the air and putting on the brakes; the overload caused by putting on the brake opens the circuit-breaker. (4) The depth indicating gear also cuts off the air, thus braking the engine drums; the excessive load opening the circuit-breaker as in the previous case. (5) Supposing the hoist is working with control lever in any running position, the driver, by throwing either of the brake levers violently over to the "brake full on" position, releases the drop weights putting on the brakes, at the same time the control lever is thrown to the mid position, disconnecting the motors electrically.

Owing to the dampness of the hoist chamber, the test on both armature and field windings was zero. After a few days the test of the field coils went up to 100,000 ohms, the effect of playing a blow-lamp flame on the outside of the field frame. A current at 250 volts from a lighting set was switched on the two field windings in series; this after a few days raised the field test to 300,000 ohms. The armatures were then treated inside the drums to a steady mild blow-lamp flame, until the test rose to 200,000 ohms, the two motors were then run in series, with all resistance in, as shunt machines at 500 volts continually reversing, using the small starting current to heat the windings, and occasionally putting on an artificial brake load of 300 or 400 amperes. This dried both motors satisfactorily, giving a test of 500,000 ohms, after which the compounding and auxiliary poles were connected and the motors run, gradually increasing the speed, until both motors were in parallel across the full line potential.

DISCUSSION.

The PRESIDENT (Mr. C. W. R. Campbell) mentioned, in connection with the drying out of the various parts of the windings, that drying, if alternating current was available, was generally rather simpler, owing to the relatively easy means of obtaining large currents at low voltage by transformation. A test immediately on finishing such drying out which gave a result of so many ohms resistance to earth, did not necessarily mean that the windings were completely dried out.

Mr. C. F. ANDERSON: With reference to the use of blow lamps for drying out motors, said the use of blow lamps, together with stoves, added greatly to the salvation of a three-phase 80 kw. machine after the considerable damage brought about by a flood early last year at the Transvaal Gold Mining Estates at Pilgrims Rest. One of the stations was completely washed away, leaving only the turbine and generator standing; all external parts were badly twisted and damaged, and the generator being totally submerged in water for several days. As soon as possible a temporary cover was rigged up and the generator thoroughly cleaned. The possibility of drying it out by incandescent lamps was out of the question owing to the distance from any source of power; such other methods as hot blast, &c., were also impossible, as owing to the weight of the machine it could not be dismantled, the crane having been washed away with the power house. The only hope, therefore, was the use of blow lamps, Premier stoves and fires. For the first three days Premier stoves and a wood fire were placed around the frame, and blow lamps in the spider of the rotor. Then the generator was run slowly with all the heating apparatus around the frame, and later the machine was short-circuited through fuses and the current increasing gradually to full load current. The generator ran a fortnight in this manner and was then put on load, gradually increasing this to full load. One coil gave out after it had been running a short time at full load, but no trouble had since arisen. This machine was supplied by Messrs. Siemens & Halske, and was at least 12 years old.

M.P. WIRING SYSTEM.

The tendency of late years in electric wiring has been towards simplicity, a state of things to a great extent caused by the high first cost of certain solid, though efficient systems, which have to a great extent precluded the use of electric light in small houses, cottages and other similar places. Many systems have been proposed to overcome this disadvantage of high first cost, while at the same time retaining the safety and efficiency of the older methods. Among the latest of these may be mentioned that due to Mr. S. W. Martyn, of Camden Town, known as the M.P. system, and described in the following article.

The M.P. system has been devised to provide a simple, cheap and reliable method of supply of electrical energy for lighting. Its component parts consist of two classes of flexible cables, viz., twin flat lead-covered cable and twin round cable armoured with galvanised iron wires, the simple fitting for mounting the switches, ceiling roses, junction boxes and wall plugs which is an ordinary wood block mounted on a metal plate with easily attached spring washers or clips for bonding purposes, and the equally simple arrangement for mounting the main fuses, the combined main switches and fuses and the distribution fuse boards which consists of a flat-shaped box with simple metal clips and spring washers inside for bonding the metallic armouring or sheathing of the cables. Either kind of the two standard types of cable can be used, the twin flat lead-covered cable being small, neat in appearance and easily bent into position; while the round armoured cable is mechanically and electrically well protected and easily erected for both surface and concealed wiring. This armoured cable can be sunk in plaster for house wiring, the armouring will, it is claimed, not unwind at the free ends before

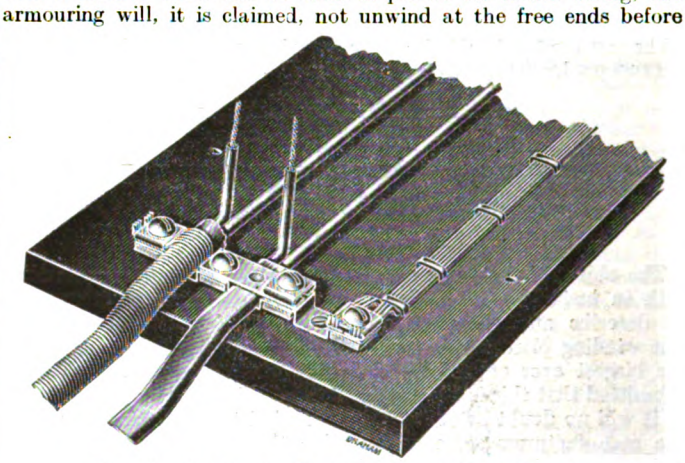


FIG. 1.—STANDARD BACK BOARD IN M.P. SYSTEM.

bonding, and it is rust-proof, owing to its being well galvanised. Cables of either type, in any required size, can be used for connecting the main fuses or combined main switches and fuses with the distribution fuse boards, and a cable of the usual 3/22 S.W.G. size has been standardised for connecting the distribution fuse boards with the standard fittings, such as the junction boxes, ceiling roses, switches or wall plugs for lighting purposes.

Fig. 1 shows a part of the back board with the two standard types of flexible cable in position. It indicates how the bonding arrangements are carried out in every case, a number of electrically connected clips being fastened together to ensure continuity. The cables are

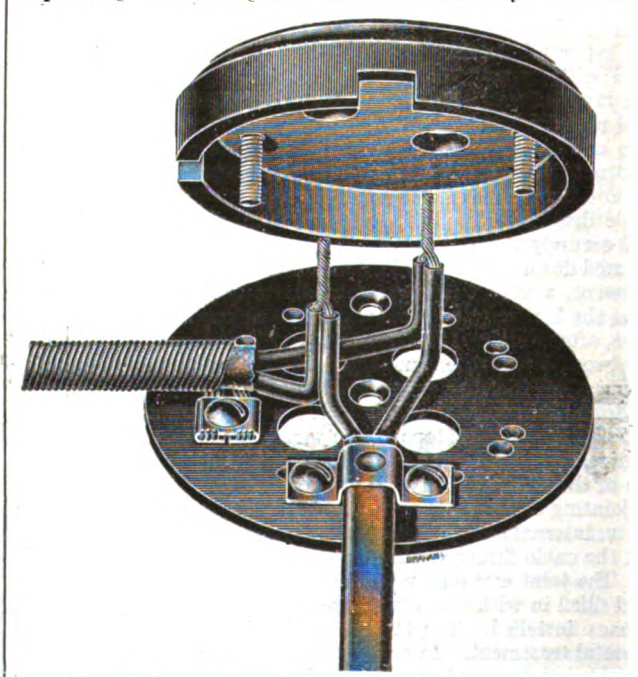

FIG. 2.—METHOD OF SIDE ENTRY TO SWITCH OR FITTING.

placed in the grooves formed by the clips being turned upside down, and in the case of the armoured round cables the ends of the galvanised iron wires are placed in simple spring washers which are held by the same bolts and nuts which hold the overlapping ends of the clips. In the case of the twin flat lead-covered cables the lead sheath is placed in the grooves of the clips and bridged over by brass plates, which are also held by the same bolts and nuts. These brass plates have holes—one in the middle of each—which allow them to be easily soldered to the lead sheath, so as to make the connections

Digitized by Google

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

thoroughly sound electrically. As many clips are used as there are cables to be bonded. If the clips are not all together, as in the case of cables entering a box from the top and bottom, the two sets of bonding clips are connected by a length of wire which is held at both ends by spring washers. The waste wire from the armouring of the round cables can be used for this purpose with the greatest success, being stapled to the wood back board as shown, and by its use there is the further advantage of having the full current-carrying capacity of the armouring throughout the system for bonding purposes. If necessary, double clips can be used, and this arrangement allows a pair of cables to enter the box side by side instead of having a small space between them.

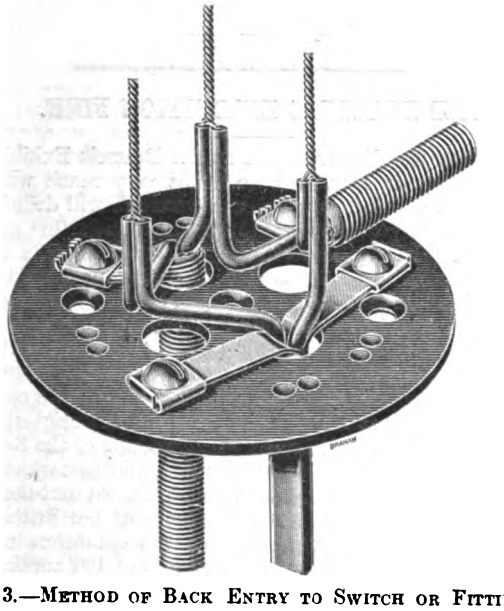

FIG. 3.—METHOD OF BACK ENTRY TO SWITCH OR FITTING.

A standard type of bonding plate is used on this system to which all the cables are connected before the wires are led to a switch or fitting. Fig. 2 shows the arrangement of this plate when the connections are from the side, and Fig. 3 when they are from the back. The back plate is of the universal kind—it provides twelve distinct paths by which a cable may enter and the necessary tapped holes for the bonding screws, eight paths from the side for surface wiring, and four paths from the back for concealed wiring. In practice this plate can accommodate eight circuits, which is an exceptional case in actual work. It has sixteen tapped holes to provide for all possibilities, four plain holes to allow the cables to come through from the back, and three countersunk holes for the wood screws which hold it in position. The wood block is of the ordinary kind, but with a large recess to make room for the bonding clips. This wood block is fixed to the back plate by two screws, as shown, which fit into any pair of opposite holes not required for bonding purposes. The twin

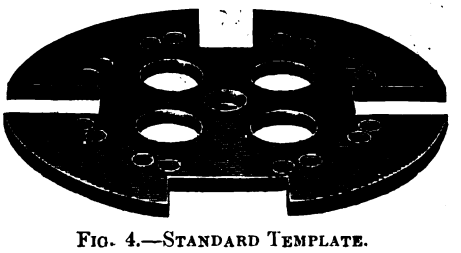

FIG. 4.—STANDARD TEMPLATE.

flat lead-covered cable is fastened to the plate by a clip and screws, and the clip is further connected electrically to the lead sheath by solder, which is put in easily through a hole in the clip, as shown. The galvanised iron wires of the armouring of the round cable have their ends placed in a simple spring washer and screwed rigidly to the plate, the live wires in all cases being brought through the block in the usual way to the fitting. In the case of the back fitting, the armouring of the cable coming in from the back is given a quarter turn so as to bring the spring washer flat against the plate for screwing purposes. The lead sheath is divided as shown, and the two portions securely clamped to the plate by a spring washer. The washers are then soldered.

The switches and ceiling rose for use with this system are of a standard pattern, all the metal parts being earthed. The introduction of the wires into these fittings is facilitated by the use of the template shown in Fig. 4. By this means the wireman can accurately and quickly mark out the position of the slots in the wood block where the cables enter. Having selected the pair of tapped holes in the back plate for holding the block (any pair not required for bonding purposes may be selected) the corresponding holes in the template are used for holding the block when being slotted out in the usual way, a round wood file being a very convenient tool for finishing off when the slot is for the round armoured cable. The three small slots in the template are used when single cables of either type enter and the wider slot when they enter in pairs. This template is in reality a back plate with the addition of four marking-out slots.

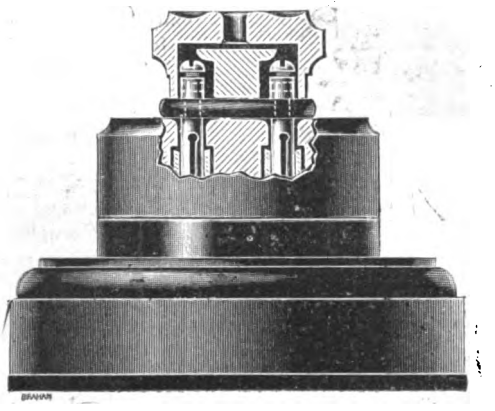

FIG. 5.—SECTION OF NEW WALL PLUG.

In this connection mention may also be made of a special safety type of wall plug designed by Mr. Martyn. The essential parts of this are shown in Fig. 5. The terminals are sunk in the socket and protected, while the cord grip arrangement enables the plug to be easily wired, at the same time relieving the terminals of all mechanical stress.

THE "BUTT" ARC LAMP.

The development of the flame arc lamp, though great, has been retarded by a number of unfortunate circumstances. It was not until this type of lamp had been on the market for some time that devices were invented for lengthening the rather short burning life, while not until just lately have attempts been made to do without the complicated mechanism of the earlier lamp.

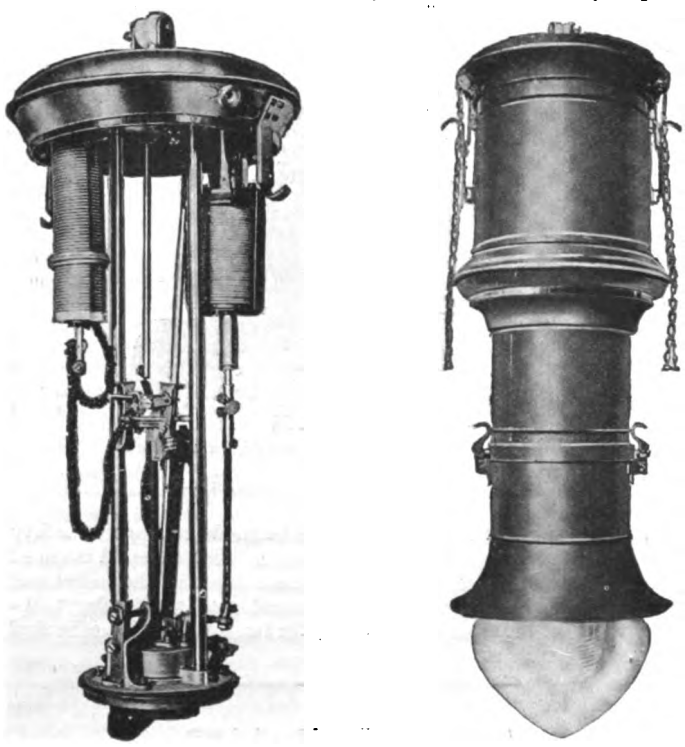
Among the latest of these attempts, and not, we hope, one of the least successful, is exemplified in the General Electric Co.'s new "Butt" lamp. This lamp is devoid of complicated mechanism and clockwork parts, and is self-regulated though without regulation coils. It has one vertical and one converging carbon. The "Butt" lamp is recommended for burning singly on 65 volts, two in series on 110 volts or four in series on 220 volts. Ordinary round-cored carbons are used, thus overcoming the great disadvantage of employing special ribbed carbons. The maintenance costs are said to be small, while there is one pattern of lamp made which is so designed and constructed as to give equally good results irrespective of the nature of the supply and current intensity. The lamp is but little affected by voltage variations, and instruments for equalising any fluctuations are quite unnecessary.

An important feature of the "Butt" lamp is its simplicity and solidity of construction. The rods are strongly dimensioned, brass nickel-plated and highly polished in order to limit the friction of carbon guides for the feed. The clutched carbon is in a vertical position in the centre of lamp; whilst the striking (inclined) carbon is under the influence of a magnet by which it can be moved laterally in order to strike and to form the arc. As the carbons are always in the same position and do not move horizontally after the arc is struck, the arc chamber is very effectively sealed against the rod chamber, and the guide rods are, therefore, kept free from deposit. The clutched carbon which controls the feed touches the incombustible lower arm of the clutch lever in the economiser. This lever is pivoted, and presses with its small upper arm above the lamp plate against the carbon. As long as the slightest weight bears on the incombustible arm, the lever grips the carbon sideways, thus relieving the fine carbon point. By progressive consumption the carbon becomes shorter, the pressure of the point on the lower lever arm decreases, and through that also the side pressure of the upper lever arm against the carbon becomes less and less, until finally the weight of the carbon overcomes the break action so that it can slide down.

Digitized by Google

The fact that the point of carbon is relieved eliminates, it is claimed, the danger of it being broken. It forms into a longer and longer point, thus raising the arc away from the lower lever arm, so that the latter cannot be burnt. The current is interrupted by the automatic discharge of the clutched carbon when consumed down to a small stump.

All lamps are fitted with conical-shaped inside globe, the use of which prevents, it is claimed, the outside globe from becoming dirty, and thus effects a considerable saving in time and labour by dispensing with the necessity for cleaning, sometimes a very complicated operation. This inner globe in no way affects the light intensity, as there is no light absorbing deposit on same. The outside globe is closed, and the air is admitted through the openings at the upper brim, passing between the inside and outside globe and rising past the ash tray into the inner globe up to the arc, forcing the fumes and deposit which form here through the high corona, directly into the open.



Long hour "Butt" Flame Arc Lamp.

The "long hour" lamp, which is mostly used for street lighting and long distance radiation, is provided with dioptric inner globe, by means of which a great lateral reflection is produced in order to obtain homogenous widespread lighting of the ground. There is only one universal pattern of "Butt" lamp for each length of carbon. The same lamp can be used for either direct, alternating or rectified current, and has only to be fitted for the respective diameter of carbons, which, of course, varies according to the nature and intensity of current. For this it is merely necessary to alter the carbon holders and carbon guide plates—an operation taking not more than a few minutes.

Short hour "Butt" Lamp.

Numerous attempts have been made since the advent of the flame lamp to produce a satisfactory pattern giving long burning hours, and owing to the great simplicity of feeding arrangements in the "Butt" double carbon lamp, and to entire absence of complicated clock work and regulating mechanism, the existing difficulties have, it is claimed, been overcome and a really safe and practical flame lamp for long burning has been obtained. With the "Butt" double carbon lamp from 32 to 38 hours' burning are obtained without any special attention being necessary, thus providing a sure means of keeping labour expenses down to a minimum. Contrary to other similar types with clock work and other mechanical regulations, the "Butt" double carbon lamp switches the arc from the first carbon pair to the second and from the second carbon pair to the first; this change occurring absolutely automatically as soon as the respective pair of carbons has been consumed, without any interruption whatever of the light. This is an exclusive feature of the "Butt" double carbon lamp, and entirely overcomes the necessity for the hitherto complicated arrangement of using carbons of different lengths according to seasons. It will be appreciated what an enormous saving in trimming and carbon costs is effected by this arrangement. This lamp is principally recommended for the lighting of railway stations, railway lines, large open spaces, streets, exhibition grounds and halls, large workshops, &c., and can be used like all other "Butt" lamps for both direct and alternating current. Two arcs can also be run in series and burn simultaneously. The illustrations show the interior and exterior of the "long hour" lamp and the exterior of the "short hour" lamp.

THE BRUSSELS EXHIBITION FIRE.

The cause of the disastrous fire at the Brussels Exhibition is as much a mystery as ever, and we doubt very much whether the official inquiry, which is now being prosecuted, will definitely clear the matter up. The past week has witnessed no further attempt on the part of the daily papers or the gas journals to affix the blame upon the electrical installation, so we may regard the old bogey as being dispelled. A vast amount of work, however, has been carried out during the week by the British Commissioner and his staff. Arrangements have been completed for the re-opening of the British exhibit section in the Salle des Fetes, and visitors to Brussels during the remaining months of the Exhibition will be given an opportunity of seeing duplicates, at any rate, of many of the original exhibits. The Earl of Lytton presided at a special meeting of the Royal Commission for the Brussels, Rome and Turin Exhibitions which was held on Saturday last, and at which it was made known that the Treasury had made a grant towards the continuance of the British section, provided that adequate response from the exhibitors was forthcoming. Since this announcement upwards of 100 applications for space in the new section have been received and the exhibits will be sent to Brussels with every possible despatch. In this latter connection it is of interest to note that the John Cockerill line, which runs steamers between Tilbury and Ostend, has placed its freight service at the disposal of British exhibitors free of all charge. This generous action should materially assist towards the re-opening of the section.

So far as the scientific instruments are concerned, most of these were of special design and cannot be entirely replaced for some little time. The manufacturers, however, are being asked to send photos and technical descriptions, which will answer the purpose in the meantime.

In the new section the utmost precautions are being taken against fire. Messrs. Mather & Platt are supplying a Grinnell sprinkler installation, and Merryweather & Sons a modern steam fire engine. A special fire brigade will also be organised for the section. In company with the British section the Belgian exhibits are being restored.

It may be noted that of the total area of the Exhibition, viz., 250 acres, only 10 acres were affected by the fire.

Emergency Electric Lighting for Ships.—According to the "Electrical Review and Western Electrician" the steamship "Alabama" of the Goodrich line, which runs between Chicago and Muskegon, has recently installed an interesting system of emergency electric lights which are furnished with current from a storage battery. These lights have been installed to provide illumination in the corridors and on the stairways in case of an accident to the generating apparatus, while, in case of the sinking of the vessel, lights would be available to aid the passengers in making their escape even after the hull of the boat had sunk some distance into the water. In order to provide illumination as long as possible in case the boat should sink, the battery has been placed at the highest point of one of the upper decks. The storage battery in use is composed of 56 cells in glass jars, having a rated output of 4·5 amperes for eight hours. This battery will supply current for 10 hours on one charge for 25 4 c.p. 110-volt carbon lamps which are in use in this installation. The battery is charged during the day, and at night, after the generators stop running, the lights used on decks, in halls and stairways are supplied with current from the battery alone. This system, it is claimed, provides a reliable source of lighting which is always available in case of accident.

BOARD OF TRADE RULES FOR PROVISIONAL ORDER APPLICATIONS.

The Board of Trade have issued, in pursuance of sec. 5 of the Electric Lighting Act, 1882, a revised set of rules with respect to applications for provisional electric lighting orders. The following extracts give all important changes in the rules:—

(I.) Every application must be made by memorial addressed to the Board of Trade, headed with short title, description of objects, &c., and the memorial must be lodged by December 21st.

(II.) In October or November applicants must publish notice of their intended application by advertisement, and this must contain, in addition to the particulars hitherto required as to objects, address and description of applicants, &c., the following information: 7.—(*a*) In the case of a provisional order to authorise the compulsory acquisition or the use of land for a generating station, a description of that land.* (*b*) In the case of a provisional order relating to the purchase of a generating station, mains or other works used solely for supplying electricity within the districts of two or more local authorities, but not situated within any of those districts, a description of the position of the generating station, mains or other works to be purchased. (*c*) In the case of a provisional order for the constitution of a joint committee or joint board, the basis upon which representation on, and the financial requirements of the joint committee or joint board and the contribution to the common fund by the constituent authorities are to be provided for.

(III.) Where a company or person applies for a provisional order for a district, and the local authority waives its right to receive (under sec. 4 (1) of the Electric Lighting Act, 1882) notice of intention to apply for an order, the waiver must be proved in the same manner as the consent to an application by a local authority.

(IV.) Any local authority, company or person intending to apply for a provisional order to authorise the distribution of electricity must, on or before November 1st in the year in which the application is made, give notice of their intended application to every company or person authorised under statutory powers to distribute electricity within the area to which the proposed application relates; and any local authority, company or person intending to apply for a provisional order to authorise the supply of electricity in bulk must, on or before the said date, give notice of their intended application to every local authority, company or person authorised under statutory powers to supply electricity in bulk or to distribute electricity within the area to which the proposed application relates.

(V.) In the case of a provisional order to authorise the compulsory acquisition of land for the purpose of a generating station, the applicants must on or before December 15th serve a notice on the owners, lessees and occupiers of all lands intended to be so acquired. Notice should be in the form set out in the schedule to the rules.

(VI.) On or before December 15th, in the year application is made for a provisional order to authorise the compulsory acquisition or use of land for the purpose of a generating station, applicants must serve notice upon the local authority of the district and upon all owners and lessees of land situate within 300 yards of the land proposed to be acquired or used.

(VII.) Notices must be in writing and must be served by leaving same at the offices of the local authority or company, or at the address of the person on or before the day prescribed, or by forwarding same by post in a registered letter, so that same would in ordinary course of post be delivered on or before that date.

(VIII.) An application for a provisional order to authorise the distribution or the supply in bulk of electricity (other than an application from the local authority of the district), or the breaking up of roads outside the applicant's area of supply, will not be entertained unless proof of the consent of every local authority within the districts in which the roads are situate to the grant of the order, or where such consent has been refused a request from the applicants asking the Board of Trade to dispense with the consent and giving the reasons for such request, must be deposited with the Board on or before February 22nd.

(X.) In regard to the deposits to be made at the Board of Trade on or before November 30th, the following are additional rules:—

In the case of a provisional order relating to the purchase of a generating station, mains or other works used solely for supplying electricity within the districts of two or more local authorities, but not situated within any of those districts, the applicants must deposit at the office of the Board of Trade a map (of not less than 6 in. to a mile) showing the area of supply, position of generating station, mains and other works to be purchased.

In the case of a provisional order for the constitution of a joint committee or joint board the applicants must deposit at the office of the Board a similar map showing the districts or parts of districts in respect of which the joint committee or joint board is proposed to be constituted.

In the case of a provisional order to authorise the compulsory acquisition or the use of land for the purposes of a generating station, the applicants must deposit at the office of the Board a plan of the site of the land and, in the case of compulsory acquisition, a book of reference. The plan must be on a scale of not less than ¼ in. to every 100 ft., and must have shown thereon any building, yard, courtyard, land within the curtilage of any building, and any ground cultivated as a garden. The book of reference must contain the names of the owners, lessees and occupiers of all lands and houses proposed to be taken compulsorily and must describe such lands and houses respectively. It must also contain the names of the owners or reputed owners and lessees or reputed lessees of land situate within 300 yds. of the land upon which the generating station is to be constructed.

The applicants must also on or before November 30th deposit a copy of the advertisement and of the said maps or plan and book of reference for public inspection at the office of the clerk of the peace for every county, riding or division, and at that of the local authority of every district to which the application relates. (In the case of a provisional order relating to the Administrative County of London, the deposit of the maps, plan and book of reference must be at the office of the London County Council.)

(XI.) In regard to the draft order, where the application is other than for the constitution of a joint committee or joint board, the draft must contain (amongst other things) a description of the proposed area of supply (if any), and, in the case of a provisional order authorising the supply of electricity in bulk, a description of the roads, railways and tramways along the route along which electric lines are to be laid for giving the supply, and in the case of a provisional order authorising the compulsory acquisition or use of land for a generating station a description of such land.

In the case of a provisional order to authorise a supply of electricity at any point within an area to be used for purposes incidental to the working or lighting of a railway, tramway or canal (other than haulage or traction or the lighting of vehicles or vessels) partly within and partly without that area, a description of the railway, tramway or canal, the names of the districts in which the electricity is to be used and a statement of the purposes for which the supply is to be given.

In the case of a provisional order relating to the purchase of a generating station, mains or other works used solely for supplying electricity within the districts of two or more local authorities, but not situate within any of those districts, a description of the generating station, mains or other works to be purchased, and a list of the districts to which electricity is supplied therefrom.

In the case of a provisional order for the constitution of a joint committee or joint board the draft order must also contain: (*a*) A description of the purposes for which the committee or board is to be constituted; (*b*) provisions for constituting the committee or board, for the appointment and removal of members, and for the meetings of the committee or board; (*c*) provisions (1) relating to the financial arrangements between the proposed constituent authorities, (2) for the appointment and remuneration of officers, and (3) for settling differences between the committee or board and any of the constituent authorities; (*d*) provisions as to audit of accounts; and (*e*) provisions for adapting the provisions of the Electric Lighting Acts, 1882 to 1909, or any provisional order in force in the area of supply or any part thereof to the case of the committee or board proposed to be constituted.

(XII.) With regard to the deposits which must be made with the Board of Trade when lodging the memorial, the following are additional requirements:—

In the case of a provisional order relating to the purchase of a generating station, mains or other works used solely for supplying electricity within the districts of two or more local authorities, but not situate within any of those districts, a list of the local authorities within whose districts the generating station, mains and other works are situate.

In the case of a local authority, in addition to the particulars required by the existing rules, a statement showing that a definite scheme (including an estimate of the cost) for the supply of electricity has been prepared and considered by the local authority, and a report by an electrical engineer on the proposed scheme.

In the case of a provisional order for the constitution of a joint committee or joint board there must be deposited with the memorial (in addition to such of the deposits hereinbefore specified as are applicable) the following particulars: (*g*) The rateable value of each of the districts of the proposed constituent authorities; (*h*) the amount of indebtedness and the borrowing powers of each of the proposed constituent authorities; (*i*) the amount of the rates in the pound in the district of each of the proposed constituent authorities; (*j*) a statement showing (where the proposal is not for the combination of existing undertakings actually worked) that a definite scheme (including an estimate of the cost) for the supply of electricity has been prepared and considered by the proposed constituent authorities and also a report by an electrical engineer on the proposed scheme; (*k*) a statement of the proportions in which the cost is to be defrayed by the proposed constituent authorities; and (*l*) a copy of any agreement between the proposed constituent authorities relating to the application.

In the case of an application other than by a local authority for an order to authorise the breaking up of roads, &c., outside the area of supply to enable electricity to be brought into that area from a generating station outside that area, there must also be deposited a list of the local authorities in which the roads, &c., are situate and a list of the roads, railways and tramways, and if the applicants are a company incorporated under the provisions of the Companies' Acts, a copy of the Memorandum and Articles of Association.

The fee has been fixed at £35 (instead of £50 hitherto required), and must be paid to the Accountant-General of the Board of Trade.

The rules also provide for deposits of copies of the draft order at certain offices in London and the provinces, and with the London County Council where the draft order affects the London area.

* At the time of proving the publication of the notice, the Board of Trade will require proof that at the date of the first publication of the notice no part of the land proposed to be compulsorily acquired belonged to any gas or water undertakers and was used or authorised to be used by them for the purposes of their undertaking. (*See* sec. 24, Electric Lighting Act, 1909.)

Digitized by Google

(XX.) In any case where the Board of Trade refuse to grant a provisional order to authorise a supply of electricity in bulk, on the ground that the matter ought to be dealt with by private bill, and the applicants intend to proceed by private bill, the notice required by sec. 4, sub-sec. 2, of the Electric Lighting Act, 1909, informing all opponents of that intention, must be served by being addressed to each opponent or his parliamentary agent or solicitor within 14 days from the date of the Board's refusal to grant the provisional order.

▶ The form of notice to landowners and others is set out in a schedule to the Rules.

PACIFIC CABLE BOARD.

The report and accounts of the Pacific Cable Board for the year ended March 31, 1910, are just issued, as ordered by the House of Commons on July 29th.

Traffic receipts for the year were £115,735. 7s. 3d., less £4,269. 18s. 9d. payment to the Atlantic companies for work done in the United Kingdom in connection with the Board's traffic, leaving, therefore, £111,465. 8s. 6d., which, with interest on deposits (£40. 16s. 8d.) and refunds (£217. 13s.), brings the total to £111,723. 18s. 2d. Ordinary expenditure came to £93,767. 6s. 9d., leaving £17,956 available for reduction of the amount (£77,544) contributed annually for interest and sinking fund on the capital advanced by the National Debt Commissioners. The amount payable by the Governments associated in the Pacific Cable enterprise is thus £59,588, against £60,888 for the previous year. The Board's contribution to the redemption fund in 1909 was £1,300 more. Traffic receipts for the year show the small increase of £403. The real increase was, however, considerably larger, as, owing to accidental delay in transfers to the Board's account by the Governments of Australia and New Zealand, £2,211 which should have been credited to the revenue for 1909-10 was not brought to account until after March 31st. But for this, the revenue would have exceeded that of 1909 by £2,614, and would have been £1,534 in excess of the estimate. In the miscellaneous receipts there was a falling off of £1,773, those of 1908-9 having been swollen by the sum received for a charter of the "Iris" (£1,339).

Expenditure for the year shows a net decrease of £2,668, the principal saving (£5,343) being ship's salaries and expenses. There was a reduction of £1,000 in amount carried to renewal account, the annual charge for which reached in the year £30,000, the figure at which it will for the future stand. There was an increase of £353 on head office expenses due to ordinary increments of salaries and to the addition to the staff of a special canvasser for London and the provinces, and another for Germany; and an increase of £3,221 for cable stations (salaries and expenses).

The preliminary forecast of revenue and expenditure for the year ending March 31, 1911, prepared December 6, 1909, was: Traffic revenue £128,000; renewal fund £30,000, working expenses £84,702, excess £13,298, total £128,000. The large increase in the estimate of traffic revenue and of working expenses is due to the new arrangements for the working of the Canadian land lines between Montreal and Vancouver. The Board, after full consideration, came to the conclusion that much could be done to minimise land line troubles if it could take into its own hands the working of the lines between Montreal and Bamfield. Accordingly, after obtaining sanction of all Governments interested, it entered into an agreement with the Canadian Pacific Railway to lease for five years the exclusive use of a copper wire between Montreal and Bamfield, the company to maintain it in good condition, and the Board to provide the staff necessary to work the line and to retain for itself such portion of the tolls as have hitherto been paid over to the railway company. This arrangement will keep a clear passage for the Board's traffic, and obviate any risk of delay from congestion of ordinary traffic over the lines of the company; it will allow of the adoption of the European system of signalling, which involves much less risk of error in transmission than does the American Morse system, and will enable the Board to make and enforce regulations of its own for early notification of any breakdown in the lines, and for the prompt diversion of messages to other routes, so as to avoid any serious delay in their reaching their destination.

For 11 months of the year under review the Pacific Cable worked without interruption, and no repairs were required. But at the beginning of March last a break occurred—the first since the cable was laid in 1902—about 3 knots from Doubtless Bay station, and caused a total interruption of communication on the New Zealand–Norfolk Island section for five days. During this period, messages to and from New Zealand were sent round by Sydney, but nevertheless a certain amount of traffic was diverted to the Eastern route with consequent loss of revenue to the Board. The injury to the cable was caused by chafing on rock, and was promptly and efficiently repaired by the Board's repairing vessel.

The health of the staff has been good throughout the year, and the service rendered by them has continued on the high level of efficiency and zeal which has characterised it in previous years.

In deference to the opinion in favour of a cheapening of cable rates for Press messages the Board offered to reduce by one-half its charge on Press messages between Australasia and Vancouver, provided the Australian and New Zealand Governments would do the same, and so allow of a reduction from 1s. to 9d. per word of the total charge between the United Kingdom and Australasia. Those Governments at once gave their assent, and the new rates were brought into force as from August 1, 1909. The effect of the change has been to increase substantially the amount of Press traffic carried by the Pacific Cable.

LEGAL INTELLIGENCE.

Wentworth & Co. v. Dean's Rag Book Co.

In the City of London Court, on Tuesday, before Judge Lumley Smith, K.C., plaintiffs claimed two guineas for supplying and fixing a number of tantalum lamps as an advertising device. Plaintiffs said defendants wanted electrical apparatus fixed with tantalum lamps for the purpose of putting it in a fountain. For that purpose the lamps had to be watertight. On Dec. 9, 1909, plaintiffs fitted the apparatus and soon afterwards had a complaint because defendants broke the tip of one of the bulbs. After Christmas the water again came in and someone had unscrewed one of the lamps. All the complaints were satisfied until April when a complaint was made that the rings were not of the right size. Some clips were put on the rings to see if that would suit defendants.

Judge LUMLEY SMITH said that the lamps were very delicate and would not stand shaking.

Evidence was given that defendants had expressed their approval of the lamps.

For the defence, it was said that the lamps had never worked satisfactorily. Water got into the lamps, causing a short-circuit, and that caused the apparatus to fail. They wanted a practical article to be sent to Manchester and other parts of the country as it was to be used as an advertising device, books being put in the windows of their customers and water played on them to show that they would not be damaged by water. They had had to get the device supplied by other electricians, who had given them every satisfaction.

Judge LUMLEY SMITH said he thought the work was experimental and had never been satisfactory. Judgment for defendants, with costs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the vacant position of assistant lecturer in the physics department of the Technical College, Sunderland. Commencing salary £150 per annum. Particulars from the assistant clerk to the Education committee (Mr. Herbert Reed), 15, John-street, Sunderland. Applications by Sept. 10. See also an advertisement.

An experienced electrical engineer is wanted for the north of England. Applicants must be conversant with latest practice in application of electric power to steel works, rolling mills, &c., and must have had experience in negotiating for and carrying out large contracts for the installation of electrical equipment. See an advertisement.

A designing engineer is required by a leading firm of turbine machinery makers. See advertisement.

A first-class fitter-erecter is required, with experience of high-speed electric machinery and of general engineering. See advertisement.

A sub-station attendant is wanted for h.t. three-phase and l.t. direct-current railway plant in London. See advertisement.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

A professor of engineering is required for the University of Queensland (Australia). Applications in duplicate to the Agent-General, 409, Strand, London, W.C., by August 31.

An assistant professor of mechanical engineering is required for the Heriot-Watt College, Edinburgh. Salary £225 per annum. Particulars from the Principal, and applications to the Clerk, 20, York-place, Edinburgh, by Sept. 3.

Wandsworth (London) Guardians require an engineer and an assistant engineer. Salaries £2. 17s. 8d. and £2. 2s. per week respectively. Applications to the Clerk, St. John's Hill, S.W., by Oct. 31.

Mr. F. E. Saunders, tramway manager at Maidstone, has resigned, to take up an appointment with Messrs. Balfour, Beattie & Co.

EDUCATIONAL NOTICES.

King's College (University of London).—In the Faculty of Engineering complete courses of study, extending over three or four years, are arranged in civil, mechanical and electrical engineering for the engineering degrees of the University of London and for the diploma and certificate of the College. There will also be special

Digitized by Google

courses of advanced lectures on "Internal Combustion Engines" and "The Theory and Practice of Construction." The entrance day for new students is Tuesday, Oct. 4.

University of Manchester.—A prospectus giving particulars of the lecture and laboratory courses in physics, preparing for both the ordinary and honours degrees, will be forwarded on application to the Registrar.

University of Bristol.—At this university complete courses of instruction in electrical, mechanical and civil engineering are given, and also instruction in the evening classes. The 1910-11 session in the faculties of arts, science and medicine will commence on Oct. 3, and in the faculty of engineering on Sept. 13. Particulars and prospectuses from the registrar, Mr. James Rafter.

A Merchant Venturer's research scholarship of the value of £50, tenable for one year, in the faculty of engineering of the University, which is provided and maintained in the Merchant Venturers' Technical College, has been awarded to Mr. Harold Heaton Emsley, B.Sc., Bristol (with first-class honours in mechanical engineering).

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

University of Birmingham.—The session 1910-11 commences on Monday, Oct. 3. The full courses in the engineering department extend over four years, and students who enter after matriculation and who pass successfully the examinations at the end of each year will be entitled to the degree of Bachelor of Science in the branch of engineering to which they devote themselves. The technical engineering classes include lectures on the strength of materials, theory of steam, gas and other heat engines, hydraulics, machine design, strength of structures and distribution of power, design of tools, prime motors, dynamos, &c. The courses in civil engineering cover a wide range. Lectures and demonstrations are given on all branches of electrical engineering and the electrical laboratory work comprises the testing of c.c. and a.c. machinery, instruments, meters, lamps and batteries and insulation and magnetic testing. The courses also include mathematics, physics, chemistry, geology and metallurgy. Syllabus, &c., from the Secretary.

University College of North Wales (Bangor).—In October a systematic course of instruction in electrical measurements and practical electricity for students proposing to enter the profession of electrical engineering will be commenced. The physical laboratory is well equipped for experimental and research work. The course extends over two sessions. Prospectus and further information may be obtained from the secretary and registrar, Mr. J. E. Lloyd, M.A.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Glasgow and West of Scotland Technical College.—The day classes begin on Tuesday, Sept. 27, and the evening classes on Thursday, Sept. 22. The diploma of the College is granted in civil, mechanical and electrical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study for the diploma usually extend over three sessions, and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow after attendance for at least one session upon prescribed University classes. Preliminary examinations begin on Sept. 19. There are new and well-equipped laboratories in the departments of physics, chemistry, mechanics, motive power and electrical engineering, &c., and facilities are afforded for research. Copies of calendar (price 1s. 4d.) and prospectus (gratis) can be obtained from the Secretary.

We have received a copy of the college calendar for 1910-11 which gives full particulars of the courses of instruction in engineering, naval architecture, &c., including evening class arrangements. The electrical engineering course extends over three years and is designed to give a sound training in the theory of electricity as well as in the fundamental principles underlying the construction and use of all apparatus required in the generation, distribution and use of electric currents. The "Sir John Pender" bursary has been awarded to Frank T. Gerstenberg for the 1910-11 session. The calendar also contains sets of examination questions, particulars of scholarships and bursaries, &c. The price is 1s., post free 1s. 4d.

South-Western Polytechnic Institute (London, S.W.)—At this Institute a complete three years' course in electrical engineering is held during the day, and a four years' course in the evening. Courses of lectures and practical work are given in a number of subjects, including elementary, intermediate and advanced electrical engineering, electrical design, instruments and lamps, alternating and polyphase currents, wiring and fitting, and the calculus for engineers. Particulars from the Secretary, Manresa-road, Chelsea, S.W.

BRITISH NOTES.

Aldershot.—The Council have obtained sanction to a loan of £2,300 for extensions of their electricity supply undertaking.

£770 for defraying excess expenditure to March 31 last and for a coal shed and mechanical stoker (loan repayable in 10 years), £1,200 for prospective expenditure on mains (25 years), and £330 for services (15 years).

Barnstaple.—In order to pay off an overdraft of £1,078 on the electricity works and to provide for some extensions of mains, &c., the Council have decided to apply for sanction to a loan of £1,970.

Belfast.—The Tramways and Electricity committee has adopted a suggestion of the chairman (Sir R. Anderson) to hold an exhibition of electric motors, lamps, electric light fittings, &c., in the Ulster Hall. The city electrical engineer (Mr. T. W. Bloxam) has been instructed to report on the matter at the next meeting.

Blackrock (co. Dublin).—The Council have asked the Board of Trade not to revoke their electric lighting order for another 12 months.

Brumby and Frodingham.—A special meeting of the Council will consider a scheme for the electric lighting of the streets at a cost of £1,100.

Bury St. Edmunds.—An inquiry was held here on Wednesday into the application of the Corporation for sanction to borrow £1,463 for an additional 200 kw. generating set, a feeder main, &c.

Dartford.—The Council have applied for sanction to a loan of £10,000 for additional generating plant at the electricity works and of £1,000 for feeders and distributors.

Electric Power in Waterworks Construction.—The "Glasgow Herald" gives some interesting particulars of the scheme for augmenting the water supply of Glasgow by the addition of Loch Arklet watershed to the existing catchment basin of Loch Katrine.

The new scheme is designed to provide an additional supply of 10 million gallons per day, and an interesting feature of the undertaking is the hydro-electric power scheme of the contractors (Messrs. Brand & Co.) for the driving of all the machinery required on the work. Not a single steam crane is in use on the workings. After careful surveys it was decided to tap the Arklet Water at a point rather more than a mile inland from Loch Lomond. From this point the water is led in steel riveted flanged pipes (21 in. diameter) along the south side of the burn round the steep hillside to a point 310 ft. above the level of Loch Lomond, and immediately over the site selected for the temporary jetty. Here the head race pipe terminates, and the water is transferred to the heavy pressure pipes, 16 in. in diameter, which are laid down the side of the hill to the power house on Loch Lomond-side. The pipe has two branches as it enters the power house, to each of which is attached a pelton wheel of 135 B.H.P., and these again drive two compound-wound d.c. electric generators of 80 kw. each. Current is generated at a pressure

Digitized by Google

of 550 volts. The effective hydraulic head is 300 ft., and either or both pelton wheels can be operated according to the power required. When working at full load about 650 cubic ft. of water per minute is used. A very efficient type of governor has been fitted to the turbines for controlling their speed. In order to provide an ample supply of water during the dry seasons the contractors have built a dam across the outlet from Loch Arklet into the burn. The electricity is conveyed by overhead cables over the hillside to the works at the dam and tunnel, where it supplies power for working all the machinery. The mechanism of the aerial ropeway is also driven by electricity. The distance from the power station at Loch Lomond to the tunnel workings is nearly six miles. The problem of transport was solved by constructing an aerial electrically-driven ropeway from Loch Lomond-side to the water-works. A pier was built on Loch Lomond-side and on it one terminal of the aerial ropeway was placed, the other terminal being situated within a short distance of the new dam. The length of the ropeway is 1½ miles, and it runs in a straight line from the jetty to the dam. At the highest point on the hill it attains an altitude of 540 ft. above the level of Loch Lomond, and from that point it descends into the Arklet Valley. The ropeway consists of two fixed burden ropes running parallel to one another and supported on steel lattice-work standards having projecting arms at the top. These arms are fitted with c.i. saddles for supporting the burden ropes. The heavier of the two ropes, which is 1¼ in. in diameter, forms the track for the loaded skips coming from the jetty, while the empty skips return on the smaller (1 in. diameter) rope. One end of each burden rope is anchored to the jetty and the other end at the unloading station at the dam is passed over a pulley and supplied with suitable tightening arrangement. To the heavier rope a weight of 26 tons is attached, and to the lighter one a weight of 16 tons. These weights are free to move up and down in a specially constructed pit. The tightening arrangement keeps the proper amount of tension on both burden ropes independent of any stretching that may be caused by the weight of the load or any expansion or contraction due to changes of temperature. Immediately underneath the burden ropes is the endless hauling rope, which conveys the load. This rope, which is of lighter section, passes round the driving drum at one end, and the tension drum at the other. The carriers of the skips are fitted with a special device, which automatically grips the moving rope as it leaves the station, and lets go on entering the station at the other end. There are 22 standards over the 1½ miles of line, of which the highest is 35 ft. The longest span between standards is 950 ft. The rope-way is driven by a 55 B.H.P. electric motor and is capable of carrying 50 tons per hour in single loads of 2 tons each. The plant was supplied by Messrs. A. Bleichert & Co. and erected by Messrs. Brand. The machinery used in the various parts of the work is all of the most up-to-date description. Rock-boring is carried out by means of small hand-hammer air drills. The drills are driven by compressed air at a pressure of 80 lb. per square inch. The compressors, which are situated at the dam and at the tunnel, are driven by 40 H.P. electric motors. There are also two electrically-driven gyratory stone crushers, which grind the rock obtained from the excavations into suitable material for concrete. By a process of screening the crushers also provide sufficient quantities of sand for the cement mortar required in the masonry work of the dam and tunnel. The concrete for the dam is mechanically prepared by a large mixer capable of turning out 30 cubic yards of concrete per hour. There are various derrick cranes on the workings at the dam, tunnel and jetty. They are all driven electrically, and vary in lifting power from 3 to 5 tons. The work is being carried out under the direction of Mr. Robert S. Grey, as agent for the contractors; while the Corporation is represented by Mr. George Smith, C.E., resident engineer.

Greenock.—The municipal electricity department commenced the supply of electrical energy to the torpedo factory on 25th ult.

A letter has been received from the Scotts Co. intimating that they will require an increased supply to the extent of 900 H.P. for driving their machinery. In view of the increase in the demand the burgh electrical engineer (Mr. J. A. Robertson) thinks it probable that a further extension of the generating plant will be required early next year.

Harrogate.—The Council have applied to the Board of Trade for an order to supply electric current to premises in the area of Knaresborough Rural Council.

Hoylake and West Kirby.—At the industrial exhibition and eisteddfod, to be held in the Hoylake Institute in November, there will be a display of electric cooking and heating appliances, &c.

Maidstone.—The tramways manager (Mr. F. Saunders) has resigned and a successor is to be advertised for at £200 per annum.

Manchester.—The L.G. Board recently sanctioned a loan of £40,000 for extensions of the electricity undertaking without holding a local inquiry.

The local Ratepayers' Association has been challenging the propriety of sanctioning a loan of such magnitude without a public inquiry, but it is pointed out that some three years ago the Board recognised the impracticability of preparing advance plans and detailed estimates for expenditure on such objects as motors and consumers' sub-stations. These things accounted for £30,000, for which the Board granted borrowing powers tentatively. These powers were recently made final on the satisfactory production of accounts of actual expenditure, plans, statements, &c., as called for by the Board.

Municipal Wiring.—Maidstone Council decided last week to support the Municipal Electrical Association in its efforts to promote a bill in Parliament giving power to local authorities who own electricity undertakings to supply, let for hire, fix, &c., fittings and wires on consumers' premises. The member for the borough has been asked to support the bill, and the Council will give financial support towards the expenses of the promotion up to £25.

Belfast Corporation have also decided to support the Bill and to make a grant (not to exceed £20) towards the expenses.

Newcastle-on-Tyne.—The Assessment committee have now agreed to reduce the assessment of the municipal tramways to the figure suggested by the Tramways committee, and the appeal to the Quarter Sessions against the assessment will be withdrawn.

The Tramways committee have under consideration the question of adopting the railless trolley system of traction in the Heaton, Gosforth and Benton districts.

P.O. and National Telephone Co.'s Staff.—On Monday, the Postmaster-General (Mr. H. Samuel) stated that there had lately appeared in some newspapers a paragraph dealing with the transfer of the business of the National Telephone Co. to the Post Office, which would take place at the end of next year—perhaps one of the most gigantic industrial undertakings that had ever been effected in this country. The paragraph stated that at that time the whole body of men and women now employed by the National Company would be temporarily unemployed, but that the Postmaster-General had undertaken to find places for about half of them with the Post Office, and that the oldest employés of the National Company would be taken on first. That paragraph was a totally incorrect assertion, which would give cause for anxiety to many thousands of homes. The whole staff of the National Company, with a few exceptions already announced and upon lines which had been well understood by the Telephone Company's staff, would be transferred to the service of the Post Office. The preliminary arrangements were already actively proceeding. No change of policy had been decided upon, and there has been no modification of the lines already announced under which the staff would be transferred to the service of the State.

Personal.—*Correction.*—With reference to a personal note on page 662 of our issue of July 29, we are informed that Mr. Arthur Greenwood, who has been appointed a director of the North-Eastern Railway Co., is not connected with Greenwood & Batley (Ltd.)

Peterborough.—An inquiry was held on Tuesday into the Council's application for sanction to borrow £2,100 for the extension of the electricity supply cables.

The chairman of the Electricity committee (Ald. Clifton) said that there were numerous applications for a supply of electricity from the district proposed to be supplied.

Porcelain Insulators.—H.M. Trade Commissioner for New Zealand (Mr. G. H. F. Rolleston) reports that a firm at Wellington wish to get into communication with British manufacturers of porcelain insulators. Communications, with catalogues and price lists, with discounts, to the Commissioner, 9, Grey-street, Wellington, N.Z.

Presentation.—The staff of York electricity works have presented Mr. W. E. Wright with a case of silver dessert spoons on the occasion of his marriage.

Railway Electrification.—It is stated that the Lancashire & Yorkshire Railway Co., encouraged by the success that has attended the electrification of their line from Aintree to Maghull, are contemplating the extension of the system to Ormskirk, and that work will be commenced shortly.

The good financial results of the electrification of the line from Liverpool to Southport has proved the efficiency of the system, and the steam service is practically superseded between all the stations from Maghull to Exchange station. The company intend, it is rumoured, to inaugurate an electric scheme which will embrace a belt route between Liverpool, Ormskirk and Southport (via Burscough Bridge), thus linking up a triangular section of the line with the electric system. To enable them to do this overhead electric cables are to be carried from the power station at Formby to a sub-station between Aughton Park Halt and Ormskirk, and for this purpose the West Lancashire Rural Council have authorised the company to cross certain roadways in their district.

School Lighting.—In the annual report of East Ham Medical Officer of Health it is stated that the gas lighting in many of the local schools is unsatisfactory. Electric lighting is recommended.

Swaythling.—The public electric lighting, due to the generosity of Lord Swaythling, was inaugurated on 15th inst.

Suicide.—An inquest was held at Crook on the 17th inst. on Arthur P. S. Adcock, 23, electrician, employed at the power station of the Newcastle-upon-Tyne Electric Supply Co. at Bankfoot, who was found dead in the sub-station there at midnight on the 15th inst. from the effects of a dose of cyanide of potassium. The jury returned a verdict of suicide by poison whilst of unsound mind.

Telephoning Telegrams.—It is reported that the recent experiment of the G.P.O. to telephone to Post Office telephone subscribers the

Digitized by Google

telegraphic messages received for them is gradually coming into favour. The experiment was begun three months ago in four London districts, and the result has justified the addition of two more districts, and within the last few weeks several more districts have been included. It is now proposed to extend the scheme all over the metropolis and to inaugurate it, on a small scale, in some of the provincial towns.

The late Harry W. Cox.—A petition to Parliament, urging that a sufficient pension be granted to the widow of the late Mr. Cox is being prepared by a committee of Hackney (London) Council.

Torquay.—Torquay Tramways Co. recently applied to the Board of Trade to appoint an arbitrator to settle the differences which had arisen between them and the Corporation in regard to the system of electric traction on the Torbay-road tramways, as the Corporation refused to consent to the company's proposal to convert the present surface-contact system to the overhead system. The Board of Trade have now appointed Mr. Archibald Reed to conduct the arbitration, which will take place in London on Sept. 12.

West Ham.—The Corporation have received sanction for borrowing sums amounting to £118,525 for their electricity supply undertaking. In 1908 the Corporation applied for power to borrow £74,000, but consent of the L.G. Board was withheld until last week, when permission was given to borrow £67,025, as well as a loan of £51,500 applied for last month. Both the applications made to the Board were opposed by the India Rubber, Gutta Percha & Telegraph Works Co., who were successful in the recent application to the High Court for a declaration that the Corporation's borrowings without the consent of the L.G. Board were illegal.

Weymouth.—A special meeting of the Council is to consider a report on the relative merits of tramways and motor omnibuses. The Electric Light committee consider the capital cost of petrol omnibuses would be £10,000, electro omnibuses £12,000, railless trolley system £12,000, and electric tramways £27,000.

Wireless Telegraph Notes.—Mr. A. Walshaw, of Otley, Yorks, is an enthusiastic wireless telegrapher, and has erected a "station" at Otley, where he has been granted by the District Council the use of a spot called the Maypole, from which elevation he is able to communicate with Cullercoats, Cleathorpes, Liverpool and other places. Mr. Walshaw is concerning himself chiefly with meteorological matters.

An additional reason for the compulsory establishment of wireless telegraph stations on board ship is urged to be the epidemic of cholera which has broken out on the Continent. Prompt intimation of the disease, when it occurs on board ship, is regarded as an extremely important matter.

The extension of the use of wireless telegraphy for improving and increasing the number of meteorological reports over a widely extended area of the world's surface is notified by the Meteorological Office. There still remains much to be done to make wireless telegraphy the useful handmaiden to this service that it can be made, and much has already been done. The principal difficulty appears to be in collating the messages so that all those that bear upon any particular point of weather prognostication may be utilised at the right moment. It seems to be a growing opinion that weather messages, of wireless telegraph origin, may prove extremely useful in aviation as heralds of the immediately coming weather in the higher atmosphere.

A French dockyard mechanic, named Debrix, working at Cherbourg, is reported to have invented a piece of apparatus by means of which Hertzian waves can be connected with a Morse telegraph circuit, admitting of Morse and wireless working being operated simultaneously. The invention is said to be under examination by the French naval authorities, the object of its application being to dispense with high-potential stations.

In the "Canadian Electrical News" for August a brief yet interesting description is given of the wireless telegraph stations on the Pacific Coast. There are 12 of these stations, two owned by the U.S. Government (at Sitka Island and at Tatoush Island), eight owned by the Canadian Government (at Digby Island, Prince Rupert, the terminus of the Grand Trunk Railway in the Pacific; Ikeda Bay, Queen Charlotte Islands; Triangle Island; Esteven Point, on the West Coast of Vancouver Island; Point Lazo, on the east coast of Vancouver Island; Tatchu Point, on the west coast of Vancouver Island, Point Grey and English Bay, Vancouver; and Victoria City), and two owned by the United Wireless Co. (at Vancouver and at Frida Harbour). The Canadian Government stations are all equipped with Marconi apparatus, the plant of these stations being of 2 kw. capacity and of 200-mile range. The three latest stations in this group are Triangle Island, Ikeda Bay and Digby Island, and the latest station to come into operation is the last-mentioned, and this is claimed to be one of the best furnished wireless stations in the world. The island is very heavily timbered. The task of clearing was a difficult one. The masts at each station are 180 ft. high, built in three sections. The tower at Triangle Island is 620 ft. high and the 180 ft. mast makes this the highest station in the world, with the exception of the Eiffel Tower at Paris. The station stands out in the Pacific 40 miles from the nearest land, on an almost barren rock, and is what may be termed the key to the wireless stations in the Pacific. It is stated that after 9 or 10 p.m. operators in the Vancouver station of the United Wireless Co. regularly interchange messages with Los Angeles, California, 900 miles distant, and that the latter station can carry on communication over 1,300 miles.

According to the shipping journals, the Wireless Telegraphy Bill introduced by Sir Edward Sassoon, making it compulsory for all vessels of a certain class to be equipped with wireless telegraph apparatus, has been withdrawn.

The latest report is that all the Turkish warships are to be equipped with wireless apparatus, and that the Turkish Government are negotiating with the Marconi Co. to this effect.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" states that the Buenos Ayres Western Railway Co. have come to a satisfactory arrangement with the Anglo-Argentine Tramway Co. in connection with the construction of the Tube from the Once to Plaza Mayo. (The subject was referred to in our last issue.)

A company has been formed in Buenos Ayres to take over the concession granted to Mr. A. Lemousin for electricity generating works in the city of La Plata. The River Plate Electricity Co. have been supplying electricity in La Plata for many years.

Australasia.—Mr. F. A. McCarty is preparing a report for the Complex Ores Co. on the proposal to construct an electric tramway over the Huon, *Tasmania*. Mr. W. F. Marshall recently visited the district on behalf of Mr. McCarty to collect information.

Ulverstone (Tasmania) Council recently accepted tenders for electric generating plant.

Launceston Council have started the installation of an auxiliary steam plant at the power station, and Messrs. Bell & Hales have been asked to advise as to the best and most economical means of increasing the water-power.

Gawler (S. Australia) Council have appointed a committee to report upon the possibility of adopting an electric lighting scheme.

The Treasurer of *Victoria* (Mr. W. A. Watt) recently announced that the Ministry had decided to include in a bill for the amendment of the Local Government Act a clause extending the borrowing powers of Councils to enable them to purchase, equip and maintain tramways. The measure will be dealt with during the present session.

The Order in Council authorising the Melbourne Electric Supply Co. to construct electric tramways in *Geelong* (Victoria) has been passed. The lease is for 30 years, to be extended by five yearly periods at the option of the municipalities.

The formal inauguration of the *Kerumburra* (Victoria) electricity works took place on 28th ult.

Electricity in Gold Mining.—In the course of the recent inaugural address the president of the Transvaal Institute of Mechanical Engineers (Mr. J. A. Vaughan) said he believed the use of purchased electric power on the mines which had contracted with the power companies for a supply would lead to a saving of 10d. per ton crushed.

This estimate relates to operations after Oct. 1, 1912, when the price per unit is to be reduced to 0·325d. for 70 per cent. load factor or over.

The mines which are not contracting have been formed into groups with sufficiently large power requirements to justify the erection of large central power stations, expect to obtain their electric power at an equally cheap rate. Mr. Vaughan states: "knowing what I do of the actual costs at the present time at one of the largest power stations on the Rand, I consider that a saving of at least 1s. per ton crushed may be anticipated, and that in a few years' time the old figure of 2s. for power costs per ton crushed will be reduced by one-half." In July the mines within the Witwatersrand district alone crushed an aggregate of 1,814,686 tons, and on the July basis a reduction of 1s. per ton in working costs would mean an addition to the profits of over £90,700 monthly, or £1,088,400 a year. Mr. Vaughan adds: "The electrification of the mines is certain to increase the proportion of white labour to coloured labour."

Finland.—The Helsingfors local tramways had a successful year in 1909, the re-laying of the lines and doubling of the track having been completed. The number of passengers carried was 6,338,00 0, against 5,094,00 in 1908, an increase of 24 per cent. The traffic receipts for the year were £37,000.

The value of the electrical apparatus imported during 1909 into Abo from Gt. Britain was £15,459, and into Hangö £4,250.

Hungary.—The Municipal Council of Kecskemet has decided to raise a loan of £62,500 for the construction of electric tramways in the district.

Digitized by Google

Imports of Electrical Goods into Australia.—A recent issue of the "Australian Mining Standard" contains particulars showing the relative values of the exports of electrical goods of various countries to Australia in 1909:—

Actual and Relative Values of Exports of Various Countries to Australia.

	Class A.	Class B.	Class C.	Class D.	Class E.	Class F.	Class G.	Class H.	Total.
	£	£	£	£	£	£	£	£	£
U.K. ..	73	51	36	58	89	41	49	63	60
Germany	19	14	30	6	11	43	31	7	17
U.S.A. ..	5	30	31	14	—	12	10	4	15
Others ..	3	5	2	2	—	4	10	26*	8
Tot. value,	£222,500	£235,500	£32,300	£29,500	£29,200	£26,500	£126,100	£115,900	£817,400

Class A.—Accumulators, arcs and carbons, cables, instruments, tapes. B—Dynamos and motors below 200 H.P. C—Dynamos and motors over 200 H.P. D—Fittings, as switches and fuses; arresters. E—Generators for direct coupling to turbines (steam). F—Rheostats and controllers; switchboards (except for telephones). G—Electric and gas appliances n.e.i. H—Telephone apparatus. * Swedish telephone exportations.

Russia.—In his report on the trade and commerce of the consular district of *Odessa* for the year 1909 Mr. Consul-General C. S. Smith states that Odessa is the principal port for importation, and also the most considerable manufacturing town in South Russia.

There is a scheme under consideration for the construction of a new grain harbour. The elevators and certain of the warehouses will have mechanical appliances for transporting the grain to other stores or on board ship, and electric lighting will be adopted on the quays.

The construction of the electric tramway system at Odessa has been begun and parts are ready to be opened for traffic. The concession is held by the Société Anonyme des Tramways d'Odessa.

It is reported that electrical enterprise in Russia seems unattractive to British firms. Electric tramways are a Belgian speciality; there are Belgian concessions or installations (or both) in Odessa, Kursk, Kharkov, Nikolaiev and Sevastopol. Electric generating stations seem to be mainly German, and the supply of electric lighting plant, &c., seem to be mainly German. One German firm is believed to have had a turnover in 1909 (mainly in the Donetz district) of about £300,000. It sold 20 steam turbine generators of 500 kw. to 1,200 kw.

In his report on the trade of *Kertch* Mr. Vice-Consul H. E. Dickie says that German manufacturers have been particularly successful in trading in the district; their methods are practically those he has recommended; their travellers speak Russian and are in touch with the people; they give reasonable credit and supply price lists and catalogues in German and Russian.

Mr. Vice-Consul C. Blakey states that the proposal of a Belgian company to convert the present horse trams at *Kharkoff* to electric traction was refused. The municipality is, however, building electric lines to compete with the horse tramways. Trade in electric lamps and fittings for Kharkoff as also in Donetz mining district and with sugar factories is considerable. Metal filament lamps are growing in favour.

In 1909 2,321 tons of electric motors, dynamos, &c., were imported into Russia against 1,934 tons in 1908, and 1,645 tons in 1907.

In *Nicolaiev* Mr. Vice-Consul J. P. Bagges states that it is proposed to raise a municipal loan of £1,000,000 for carrying out various undertakings, the chief of which are the buying out of the existing horse tramways and the electrification of the system, the construction of new lines, port improvements, &c.

Mr. Vice-Consul Young states that a concession for the construction of an electric tramway at *Simferopol* has been given to the Belgian company which owns electric tramways and lighting undertakings at Sevastopol.

Spain.—Owing to the availability of abundant water power, electrical energy is extensively used in the province of Granada, mainly for lighting. There are three power stations in the town of Granada, and about a dozen smaller stations in the province. Plans are being drawn up for the utilisation of other large waterfalls in the Sierra Nevada, with the object of supplying electrical energy to the neighbouring provinces.

Uruguay.—The Government have approved the proposed reduction in the price of electric current supplied to industrial establishments in Montevideo. The new rate is to be two cents gold per unit when the total consumption of any consumer exceeds 2,000 units per month.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Acton.—The Borough Accountant, in his annual report, states that there was a satisfactory decrease in the deficiency on the electricity undertaking from £4,943. 17s. 10d. in 1908-9 to £675. 1s. 2d. for 1909-10.

The reduced charges made by the Metropolitan Electric Supply Co., which came into operation on July 1, 1909, resulted in the Council obtaining 242,468 more units than in the previous year for a decreased payment of £762. 18s. 6d. The average price paid for each unit purchased from the company was 0·86d., against 1·26d. The Council were also fortunate in not having to expend any considerable amount on repairs to transformers and machinery, and the expenditure on new meters and installations, which although in the nature of capital expenditure, are paid for out of revenue, was £427. 13s. less than in 1909. The sales increased by 188,004 units of which increase 79,273 units are accounted for by the reinstatement of the electric street lighting on the main roads and 95,824 units for sewage pumping. Although the charges to ordinary consumers for lighting units were increased by 1d. per unit, the average amount realised per unit was only 3·38d. against 3·33d. The total cost to the Council of each unit sold, exclusive of loan charges, was 2·24d. against 3·51d., and the gross profit on the year's working was equal to 1·32d. per unit sold. The expenditure during the year on capital account (principally on mains and services) was £1,167. 2s. 7d. A further loan of £7,000 was raised, and after crediting repayments, the total debt at the end of the year was £66,088. 5s. 3d.

Exeter.—The accounts of the Electricity undertaking for the year ended March 31 show total income of £18,235, including £12,827 for the sale of current for private lighting and power, and £4,386 for traction.

The expenses were £8,211 and the gross profit was £10,024. Interest came to £2,822, and sinking fund £4,118, and after paying income tax (£157) the net profit (£2,927) was carried to reserve and renewals account. The gross capital expended was £108,346, an increase of £1,138. 815,044 units of current were sold for private lighting and power (607,399), and for public lighting (203,704), and by contract (3,941). There are 47 arcs and 499 incandescents for public lighting, and electric current is also supplied to three public clocks. 637,679 units of current were generated for traction, and 598,718 units were sold to the department, 38,961 units being used on the works. The total maximum supply demanded was 740 kw. for lighting and power and 400 kw. for tramways.

The traffic receipts of the tramways department were £16,929 (9·563d. per car-mile), and the working expenses £11,296, leaving a gross profit of £5,633. After paying loan charges (£2,537), income tax (£41) and contribution to sinking fund account (£1,631) the balance profit (£464) was carried to reserve. 4,097,133 passengers were carried and 424,873 car-miles run.

Ipswich.—The total income of the electric supply department for the year ended March 31 was £17,202, including £13,694 from the sale of electrical energy for private and public lighting, power, and traction and £3,043 from the installation department.

Total expenses were £10,162 and the gross profit was £7,039. Interest on loan came to £2,397, bank interest to £603 and cost of loans £40; redemption of debt charges were £2,918, second instalment of preliminary expenses was £240 and final instalment of cost of renewal of boiler settings £105, and with £166 brought forward the balance was £902. The total capital expenditure was £89,042, an increase of £2,027. 1,543,044 units of current were sold, including 456,395 units for private lighting, 322,988 for power, 757,948 for traction and 5,713 units for public lamps. The total maximum supply demanded was 944 kw.

In the report of the chief engineer and manager (Mr. F. Ayton) it is pointed out that the net profit on the year's working is £1,080. 6s. 5d., and, excluding the installation department, the revenue increased by £1,457. 10s. 7d. (11·5 per cent.) over 1908-9, while the expenditure only increased by £329. 10s. 11d., or 4·7 per cent. The units sold increased by 10·2 per cent.; the increase in lighting units was 24·9 per cent. and for power (excluding traction) 8·9 per cent. The free wiring (rental) system has been in operation for upwards of two years and during the past year had been the means of obtaining 51 out of the 128 new consumers connected. The profit on the installation department was £166. 8s. 11d.

The total revenue of the tramways department was £20,883 and the traffic receipts were £20,304. The total working expenses were £16,590, leaving a gorss profit of £4,293. Interest absorbed £3,917, redemption of debt charges were £1,908 and preliminary expenses £200, leaving a deficit of £1,732, against £2,294. The total capital expenditure is £114,431. 5,006,881 passengers were carried and 644,786 car-miles were run. The percentage of working expenses to receipts was 79·44 against 81·23.

Nelson (Lancs.)—The total income of the electricity supply department for the year ended March 31 was £9,525, including £8,810 from the sale of electricity for lighting, power and traction.

Working expenses were £5,114 and gross profit £4,411 (against £4,561 in 1909). After paying interest (£1,885) and sinking fund instalment (£2,657) there was a net deficit of £132, against a profit of £36. Total capital expended was £74,701, increase £534 during the past year: the sinking fund instalments amount to £19,326. 936,580 units of current were sold (against 889,573), including 292,128 for private lighting (against 267,464), 77,337 for power (65,188), 284,649 for tramways (303,006), 254,912 for light railways (231,926) and 27,554 by contract (21,989). The equivalent of 34,500 8 c.p. lamps is connected (against 31,578), and there are motors of 310 H.P. The maximum supply demanded was 855 kw. (745 kw.).

The total revenue of the light railways department was £7,163. Expenses were £5,994, leaving gross profit £1,169 to meet interest (£1,069) and sinking fund instalment (£872), the net deficit being £771. The capital expended is £35,730. 2,001,538 passengers were carried and 200,115 car-miles run. The traffic revenue was 8·56d. and the working expenses 7·19d. per car-mile.

Portsmouth.—The income from the sale of current for public and private lighting during the year ended March 31 was £46,145, against £47,264 in 1909. The total income was £47,194, against £48,631.

The total expenditure was £24,321, against £24,442. 2s. 10d., and the gross profit was £22,873 against £24,189. Interest required £9,984, instalments of principal repaid £10,653 and income tax £436, leaving a net profit of £1,801 (against £3,930) of which £1,500 was voted in relief of rates. The total capital expended is £334,818, an increase of £4,034. 3,521,570 units of electric current were sold, including 2,721,021 to private consumers by meter, and 3,248 by contract, and 797,301 units were supplied to the public lamps (267 large and 142 flame arcs and 472 incandescents). The total maximum supply demanded was 2,790 kw.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

LITTLEBOROUGH District Council invite tenders for the supply and delivery of alternating-current (single and three-phase) electricity meters. Specifications and forms of tender from the clerk to the Council (Mr. Geo. H. Wild). Specifications may be seen (but not obtained) at the offices of the consulting engineers (Messrs. Hawtayne & Zeden), 9, Queen-street-place, London, E.C. Tenders, addressed to Mr. Wild, at the Council offices, Littleborough, by Tuesday, Sept. 13. See also an advertisement.

ALDERSHOT District Council invite tenders for supply of one chain grate mechanical stoker to be delivered and fixed at their electricity works. Further particulars and specification from the electrical engineer (Mr. F. Garside), and tenders to the Clerk to the Council (Mr. W. E. Foster), Municipal Buildings, Aldershot, by 6 p.m., Tuesday Sept. 6. See also an advertisement.

By command of the POSTMASTER-GENERAL tenders will be received until noon, Monday, Sept. 26 for supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles to be delivered at one or more of the ports set out in an advertisement in another column. Forms of tender from the Controller of Stores (Mr. G. Morgan), Stores Dept., G.P.O., 17-19, Bedford-street, London, W.C.

The POSTMASTER-GENERAL also requires tenders (by noon Sept. 26) for creosoting, &c., telegraph poles. Forms of tender, &c., from the Controller of Stores, 17-19, Bedford-street, London, W.C.

The Calcutta Electric Supply Corpn. is prepared to receive tenders for supply, delivery and erection at their Cossipore station and sub-stations, CALCUTTA, of motor-generators, turbo-alternators and condensing plant. Copies of specifications, drawings and general conditions from the secretary (Mr. Francis R. Reeves), Salisbury House, London Wall, E.C., to whom tenders by 10 a.m. of Sept. 19. See also an advertisement.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms, &c., may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 5 for the supply of 5,000 porcelain insulators to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Oct. 4 for the supply of telephone material to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W.

Tenders will be received (up to 3 p.m. Sept. 13) by the Deputy Postmaster-General, MELBOURNE, for supply of 8,510 telephones. Local representation necessary.

The Deputy Postmaster-General, SYDNEY (N.S.W.), invites tenders (until 2:30 p.m., Oct. 5) for supply of 5,000 porcelain insulators. Local representation necessary. Specifications, &c., from 72, Victoria-street, London, S.W.

LONDON County Council invite tenders for the covering with asbestos tape of certain electric cables in manholes in the south of London. Specification, drawing, form of tender, &c., from the Clerk of the Council, Mr. G. L. Gomme, Spring Gardens, S.W. Tenders by 11 a.m. Aug. 30.

LONDON County Council also invite tenders for wiring and fitting for electric lighting of the second section of the central car repair depot, Woolwich-road. Specifications, &c., from the Clerk of the Council. Tenders by 11 a.m. Tuesday, Aug. 30.

BOURNEMOUTH Tramways committee want tenders by Aug. 31 for reconstruction of 2½ miles of tramway permanent way and supply of 450 tons of rails, with fastenings. Specifications, &c., from the General Manager.

ROCHDALE Tramways committee want tenders by 9 a.m. Aug. 31 for the construction of 1 mile of permanent way for Whitworth tramway extension. Forms of tender from Mr. J. S. D. Moffet, Tramway Offices, Mellor-street, Rochdale.

ROCHDALE Electricity committee want tenders by noon, Aug. 31 for 12 months' supply of paper insulated cables. Specification from the engineer and manager.

KIRKCALDY Corporation want tenders by Aug. 29 for the extension of the tramways to Dysart. Specification, &c., from the Burgh Surveyor.

CHELMSFORD Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

POPLAR (London) Guardians want tenders by 6:30 p.m. Aug. 31 for 12 months' electrical supplies, ironmongery, packing and jointing, &c. Forms, &c., from the Clerk.

WEST HAM Guardians want tenders for 12 months' supply of electrical fittings, engineers' oil, &c. Tenders to the Chairman of the Board, at 11 a.m., Sept. 1.

The directors of the Powell Duffryn Steam Coal Co. (ABERDARE) invite tenders for stores, including electrical goods. Tenders to London office (101, Leadenhall-street, E.C.) by Sept. 12.

HACKNEY (London) Council want tenders by 7 p.m. Sept. 15 for extension of main switchboard. Specification from Town Clerk, Town Hall, Mare-street, N.E.

MANCHESTER Tramways committee invite tenders (until Sept. 6) for supply of steel girder tramway rails.

SALFORD Corporation invite tenders for supply and delivery of a vertical steam-feed pump. Tenders by noon Sept. 12.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British

Digitized by Google

firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

MOSTAR (Austria-Hungary) municipality will receive tenders until Oct. 1 for the installation of electric generating plant.

Tenders are required for supply of machinery and tools intended for the workshops of the Directorate of Hydraulic Works, Buenos Ayres. Tenders to Dirección General de Contabilidad, BUENOS AIRES, by 3 p.m. Oct. 10.

Tenders are invited by the ITALIAN State Railways Administration for the following:—

One rolling machine for sheet metal, worked by an electric motor, for the workshops at Rimini, and 12 cranes for Turin workshops. Tenders by Sept. 13 to the Direzione Generale delle Ferrovie dello Stato, 16, Via Ludovisi, Rome. (Only those firms (Italian and foreign) on the list kept by the Administration are allowed to tender, and generally only when invited. Local representation is practically necessary.)

TENDERS RECEIVED AND ACCEPTED.

Rawtenstall Council have accepted the following tenders for the construction of the Whitewell tramways:—

Clough, Smith & Co., overhead equipment; W. T. Glover & Co., cables, ducts, &c.; Wm. Underwood & Bro., permanent way construction.

West Ham Education committee have accepted the tender of J. T. Halsey (lowest tender) for the electric lighting of West Silvertown schools at £287. 17s. 6d. (Eight tenders received; highest £1,500.)

The tender of the Worthington Pump Co. for a surface condensing plant and oil separator with accessories, at £400, has been recommended for acceptance by Belfast Harbour Commissioners.

Maidstone Corporation have accepted the tender of Arthur Lowcock (Ltd.) for supply and erection of a fuel economiser at the electricity works at £343. 10s.

Crewe Education committee have accepted the tender of Carrington & Button for supply of electric light fittings for their Bedford-street schools.

The Steeplejack & Engineering Co. (Nottingham) have received instructions from the City of London Electric Light Co. to carry out extensive repairs to their two large chimney shafts at Bankside.

The tenders of J. Banks for a dynamo, &c., and the National Gas Engine Co. for a gas engine for the electric lighting of the large hall at the Town Hall, Skipton.

Dartford Council have accepted the tender of the Baker Oil Separator Co. for an oil separator at £167. 15s.

Maidstone Council have placed an order with Arthur Lowcock (Ltd.) for a fuel economiser at £343. 10s.

Canterbury Guardians have accepted the tender of F. A. Parry for wiring the Woodvill Children's Homes.

The tender of Sutherland & Ashman has been accepted for the supply and erection of electric lighting plant at Ulvertone (Tasmania) at £4.487. 5s. 11d.

Sydney (N.S.W.) Council have accepted the tender of Stewarts & Lloyds for supply of steel poles for the Annandale lighting contract at £1,709. Delivery is to be made in 12 weeks.

An order has been placed by Sydney (N.S.W.) Council with W. T. Henley's Telegraph Works Co. for 15 miles 11,000-volt cable for the electric lighting of Bunnerong-road, Randwick, and Long Bay Penitentiary, and other Government buildings in Randwick municipality (N.S.W.), at £4.760. Three tenders were received. Noyes Bros. (tendered at £5,317. 8s. 3d.) and British Insulated & Helsby Cables (£6,735).

Sydney (N.S.W.) Municipal Council recently received the following tenders:—

For supply and erection of coal and ash-handling plant at new boiler house at the electricity works, Babcock & Wilcox tendered at £5,887. 5s. and Gibson, Battle & Co. £8,798.

For house service fuse boxes, Noyes Bros., Lawrence & Hanson, India Rubber, Gutta Percha & Telegraph Works Co., W. G. Watson & Co., Haes & Eggers and British Insulated & Helsby Cables tendered.

For generator cables the tender of Noyes Bros. (£1,763. 8s. 9d.) was recommended for acceptance; W. T. Henley's Telegraph Works Co. (£1,852) and British Insulated & Helsby Cables (£1,986. 1s. 3d.) also tendered.

For contract and suspension gear, W. G. Watson & Co. (£525) and Noyes Bros. (£580) tendered; and for arc lamp winches W. G. Watson & Co. (at schedule rates) and Noyes Bros. (£163. 4s.) competed.

For the supply of 250 tons bitumen the quotation of the Patent Asphaltum Co. at £1,113. 15s. was recommended for acceptance.

Staerker & Fischer have secured the contract for the sub-station equipment of the Launceston (Tasmania) electric tramways at £3.302. 17s. 6d.

The contract includes two synchronous motor-generator sets, each consisting of one 5,000-volt 50-cycle synchronous motor, three phase, running at 500 revs. per min., direct coupled to shunt-wound continuous-current dynamos, with auxiliary poles, of 100 kw. capacity (500 to 600 volts), h.t. switchboard control panels, high-tension cubicle construction and battery booster switchboard. The booster will be of the A.E.G. Pirani type, and the battery of 266 Tudor cells, having a discharge capacity of 185 amp.-hours. In addition, the firm are also supplying spares and extras at £881. 17s.

Messrs. Stewarts & Lloyds are to supply tubing and brackets for the Launceston (Tasmania) tramway sub-station at £60.

Haes & Eggers (Sydney, N.S.W.) have received an order for the supply and erection at Ultimo power house (Sydney) of two centrifugal circulating pumps, capable of pumping 9,000 gallons per minute to a head of 60 ft.

The pumps are 22 in. motor-driven centrifugal type, and the motors will be supplied by the Australian General Electric Co., and will be of 260 B.H.P. each.

Haes & Eggers have also received an order for two 60 H.P. variable-speed d.c. motors for operating air compressors. The motors will be supplied by the Lancashire Dynamo & Motor Co. and the pumps will be manufactured by Gwynnes (Ltd.).

The tender of F. A. McCarty & Co. (£60,973) has been accepted for the construction of the permanent way of the Adelaide (S. Australia) outer area tramways.

Commonwealth Tenders.—The following tenders have been accepted by the under-mentioned Government departments of States of the Commonwealth:—

Postmaster-General's Dept. (*N.S.W.*)—Western Electric Co. (Australia), 100 party line keys, at 18s. each; 100 party line relays, at 7s. 8d. each. India Rubber, Gutta Percha & Telegraph Works Co., 18 pole changers (telegraph, electromagnetic), £5. 15s. each; 12 differential galvanometers, £4. 15s. each; 12 transmitters (telegraph), £4. 5s. each.

W. Australian Railway Dept.—General Electric Engineering Co., 243 Osram lamps, £39. 9s. 9d.

Government Contracts.—During the past month the following contracts were among those given out by the Government Departments mentioned:—

War Office.—British Insulated & Helsby Cables, conductors and supports for Aldershot electricity supply; Electric Construction Co. and Siemens Bros. Dynamo Works, electric motors; G. E. Taylor & Co., wiring Ewshott Camp Institution.

India Office.—Pritchetts & Gold, accumulators, &c.; J. Stone & Co., dynamos, &c.; Lancashire Dynamo & Motor Co., electric motors; Morgan Crucible Co., plumbago.

G.P.O.—Gent & Co., house telephone apparatus; British Insulated & Helsby Cables and W. T. Henley's Telegraph Works Co., i.r. and cotton core cable; Johnson & Phillips and Callender's Cable & Construction Co., paper core cable; India Rubber, Gutta Percha & Telegraph Works Co., submarine cable; Siemens Bros. & Co., supply and laying of cable, and also dry cells; Bullers (Ltd.) and J. Bourne & Son, insulators; T. Bolton & Sons and F. Smith & Co., bronze wire; British Insulated & Helsby Cables, T. Bolton & Sons, Elliott's Metal Co., R. Johnson & Nephew, Shropshire Iron Co., F. Smith & Co. and Wilkes, Sons & Mapplebeck, copper wire.

H.M. Office of Works.—T. Clarke & Co., wiring Edinburgh Royal Scottish Academy.

Water-Tube Boiler Contracts.—Messrs. Clarke, Chapman & Co. (Ltd.), of Gateshead-on-Tyne, have recently received some large and important orders for their Woodeson patent water-tube boilers, including the following:—

Large installation of boilers for extensions to the generating station at Devonport Dockyard (a repeat order from the Government for this type of boiler during the last 12 months); two large boilers for W. Sommerville & Sons' paper works; four boilers for utilising the waste gases from coke ovens for the Nunnery Colliery Co.; four boilers for utilising waste heat from re-heating furnaces for Wm. Cooke & Sons; four large boilers for Sir B. Samuelson & Sons (Middlesbrough) to work in connection with blast furnace gases; one boiler to utilise the waste heat from re-heating furnaces for Brown, Bayley & Co.; one large boiler for Luton Corporation; and one boiler for Whitehaven Colliery (the third repeat order from this company).

The above orders, together with a large number of boilers booked during the previous few weeks for various parts of the country are keeping Messrs. Clarke, Chapman & Co.'s boiler yard well employed, and speaks well for the success of the Woodeson boiler. It is generally admitted by steam users that for economy, ease of accessibility and efficiency this is one of the most successful boilers on the market. All the above-mentioned orders are for this country; there are several large orders in hand for Continental and other foreign countries.

BUSINESS NOTICES.

Mr. C. A. B. Pyne (late of Messrs. Balmer, Lawrie & Co., Calcutta) and Mr. E. M. Hughman (for 12 years with Messrs. Robert Hammond & Son, consulting engineers, Westminster, and late of the County of London Electric Supply Co.) have entered into partnership as electrical engineers and contractors, under the style of Pyne, Hughman & Co. Mr. Archibald Gall (late of Messrs. James Hodgkinson (Ltd.), Manchester, and formerly of Messrs. Andrew Yule & Co., Calcutta) has joined the staff as chief engineer. The headquarters of the firm are in Calcutta, and the London office at 95, Leadenhall-street, E.C.

Communications for the secretary of the Incorporated Municipal Electrical Association should be addressed to Mr. C. McArthur Butler, 28, Bedford-square, London, W.C.

Messrs. Ferranti Limited notify that their works and offices at Hollinwood will be closed for the annual district holidays from this (Friday) evening, until Monday morning, Sept. 5, a small staff being retained to deal with urgent correspondence.

In order to cope with the continued increase of business, Messrs. Babcock & Wilcox have found it necessary to extend their works at Renfrew, and they are erecting three large additional shops, each 300 ft. long by 60 ft. wide.

The shops will be fully equipped in the most modern style. Two of them are required for the manufacture of mechanical stokers and coal-handling plant, and the third is needed in connection with the manufacture of marine boilers, for which the demand is rapidly increasing, large orders being in hand for boilers for battleships and cruisers for the British, Colonial and Foreign Governments, while several important contracts have been secured recently for boilers for the mercantile marine.

Electrical Cookers.—The manufacturers of "Tricity" cookers which have been steadily perfected for use on both d.c. and a.c. circuits have appointed Messrs. Gillespie & Beales, Amberley House, Norfolk-street, Strand, W.C., as sole wholesale agents. Messrs. Gillespie & Beales are now appointing local agents. Provincial contractors should make a note of this forward move on the part of the Berry Construction Co., and should communicate with their wholesale agents, if they have not already done so.

Plant Wanted.—Mr. Thomas Johnson, Prescott-street, Wigan, requires a 300-400 kw. generating set, 500 volts.

"Osrams" for Public Lighting.—One of the finest examples of street illumination by means of metal filament lamps is that of the

OSRAMS ON O'CONNELL BRIDGE, DUBLIN.

famous O'Connell Bridge at Dublin, which serves at night the useful purpose of a directing sign to travellers requiring to go in this direction.

Anyone familiar with this part of Dublin must be greatly impressed by the radical change for the better that has taken place since the conversion of the lighting arrangements from gas to Osrams. The present result is obtained by quite a small number of lamps. In all, 39 100-volt 55-watt Osram lamps are used, these being fitted in the old lanterns originally put up by the gas company and which have since been converted for their new use. It will, of course, be appreciated that in such a position the lamps are very exposed, and naturally encounter more than an ordinary share of rough weather. We learn that they have proved fully capable of withstanding this treatment, and up to the present the Corporation consider they have behaved remarkably well. The illustration herewith, which has been reproduced from an untouched photograph, is rather of the freak order, owing to the long exposure necessary. The regular lines shown running across the centre of the picture are occasioned by the headlights of tramcars, which were continually passing up and down while the photograph was being taken. The installation is of particular interest, however, on account of its exposed position.

Patents Development.—The owners of patents No. 23,501/1899, relating to "Improvements in vacuum table lighting," and No. 12,582/1902, relating to an "Improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Information from Messrs. Lloyd Wise & Co., 46, Lincoln's Inn Fields, London, W.C.

Telegraphone Patents.—The owners of certain telegraphone patents (Poulsen's, Pedersen's and Schou's) desire to grant licences or to enter into arrangements for working same in this country. Particulars from Messrs. W. E. Heys & Son, Patent Agents, 51, Deansgate-arcade, Manchester. See also an advertisement.

"Faraday House Journal."—The August issue of this journal contains interesting technical articles, including one upon the "Commercial Production of Aluminium," and another upon "Electrically-Driven Winding Engines." The adoption of electrical winding in this country is receiving considerable attention from colliery managers at the present time. We note also that students of Faraday House appear to obtain substantial appointments when their time has expired.

Workshop Wrinkles and Recipes.—Messrs. Percival Marshall & Co. have ready No. 10 of their practical manuals with the above title. This is useful for amateur workers, and contains many of those little tips which it is impossible to carry always in one's head. It is cheap at 1s.

CATALOGUES, &c.

ELECTRIC LAMPS.—We have received from Messrs. L. E. Wilson & Co., Manchester, an illustrated catalogue showing the various types of the small electric lamps made by them. Full details of these useful apparatus are given. They are fitted with small accumulators, and are finding a wide application among householders, doctors and motorists.

BARWICK SWITCHGEAR.—We have received from Messrs. Donovan & Co. a pamphlet dealing with Barwick switchgear and fuses and electric light accessories of various kinds.

ELECTRICITY FOR ALL INDUSTRIAL USES.—The Union Electric Co. have just issued a very well illustrated pamphlet dealing with this subject. It contains illustrations of typical Union plant and also shows the shops in which these useful equipments are made. The ranges covered by the Union motors are apparently very wide and vary from such large work as bending and straightening rolls, saws, traversing tables and other similar plant to small table fans.

SWITCHGEAR.—Messrs. Cowans (Ltd.) send us a series of leaflets dealing with switchgear made by them. These illustrate and describe circuit-breakers, relays, fuses, rheostat, starting switches and transformers.

MINING PANEL.—We have received from Messrs. A. Reyrolle & Co. a pamphlet describing a type of mining panel which is now being manufactured by them. The isolated switch on this cannot be re-opened until the corresponding oil-switch has been put in the off position, while the oil switch cannot be closed while the isolating switch is in the off position. Each door is also locked so that it cannot be opened until the pressure has been cut off by the isolating switch. These panels have been designed to accommodate current and potential transformers and the fronts can be fitted with any combination of instruments required.

TELEPHONE APPARATUS AND SUPPLIES.—The Western Electric Co. have sent us a very complete catalogue dealing with this subject. It is claimed to be one of the most complete yet issued, and in it are to be found all the latest systems including those for the central battery system. Any firm doing business in telephone work should apply for a copy of this list.

BANKRUPTCIES, LIQUIDATIONS, &c.

The first meeting of creditors of Fredk. Peacock, electrician, 59, North Station-road, Colchester, will take place on Sept. 9 at the Cups Hotel, Colchester, and the public examination on the same date at the Town Hall, Colchester.

Frederick Peacock, electrician, 59, North Station-road, Colchester, has been adjudicated bankrupt.

The Telewriter Synd. (Ltd.) is being wound up voluntarily, the telewriter and other assets having been sold to the National Telewriter Co. A meeting of creditors was held on 24th inst.

23,719 BULT. (Acme Automatic Street Indicating Co.) Electric circuit closing devices on electric railways and the like.
23,937 MONNIER. Distributing box for cables with multiple electrical conductors. (Date applied for, 19.10.08. Request under sec. 19 not granted.)
23,938 FORTESCUE. Electrical transformers. (Date applied for, 19.11.08.)

COMPANIES' MEETINGS AND REPORTS.

ABERDEEN SUBURBAN TRAMWAYS CO.—The directors' report for the half-year ended June 30 states that the profit was £1,260. A dividend of 2½ per cent. is declared for the past year.

BOLCKOW, VAUGHAN & CO. (LTD.)—In the directors' report it is stated that the total expenditure upon new bye-product ovens, exhaust steam turbines, electrical installations, new ironstone mine machinery, extensions, &c., during the past year was £173,602. 13s. 4d. A dividend bringing the amount for the year to 6 per cent. is declared.

BRITISH CONTINENTAL ELECTRICITY CO. (LTD.) (SAN REMO).—During the past year 171 new installations were connected, and the number of equivalent 8 c.p. lamps added was 1,295 (motors calculated in equivalent lamps). The output of electricity has increased, and the working expenses been reduced. The extension of the company's network to the neighbouring village of Poggio has now been carried out. After allowing for depreciation, the balance standing to credit of revenue (including sum brought forward) is £1,670. 8s., which the directors recommend shall be carried forward to meet payment of future dividends, the amount having been temporarily appropriated to capital account, pending the issue of further capital

NAIROBI ELECTRIC POWER & LIGHTING CO. (LTD.)—The accounts for the period to Dec. 31, 1908, included only the first few months of revenue earning period, and the working expenses at Nairobi were considerably in excess of receipts, making a net working loss of £1,233. 11s. 11d. The steady progress of the operations during 1909 has resulted in the receipts being slightly in excess of all working expenses there. There has been considerable further expenditure on capital account, and this is still proceeding. At June 30 last there were 228 customers (against 178 at end of 1909), and the equivalent of 4,728 8 c.p. lamps was connected (against 3,628), the connections for street lighting being 1,192 (against nil). There were also motors of 228 B.H.P. (against 178 B.H.P.

YORKSHIRE ELECTRIC POWER CO.—The directors in their report for the half-year ended June 30 state that the growth of the business is proceeding steadily and satisfactorily. The customers have increased their demands, and a number of important new customers have been connected during the half-year. The receipts from the sale of energy and for work charged to consumers, &c., for the half-year were £16,675. 10s., against £11,169. 4s. 2d. for the corresponding half-year of 1909, and £8,698. 9s. in 1908. The gross profit for the half-year is £4,950. 3s. 6d., against £2,598. 12s. 11d. in 1909 and £1,249. 16s. in 1908. After payment of mortgage interest (£799. 10s. 10d. more than the corresponding half of last year) the net revenue account shows a profit of £2,621. 17s. 8d., compared with £1,069. 17s. 11d., in 1909 and £363.6s.10d. in 1908. Further remunerative business is being pressed upon the company in districts not yet covered by their mains, but further capital is required for this. An extraordinary meeting will be held to pass a resolution sanctioning the terms of issue.

NEW COMPANIES, MORTGAGES AND CHARGES, AND RECEIVERSHIPS.

NEW COMPANIES.

CARTMAN & CO. (LTD.) (111,363).—Reg. Aug. 18, capital £5,000 in £1 shares, to take over the business of electric piano and musical instrument manfacturers and merchants carried on as the Tel Electric Co., and to adopt an agreement between C. E. Cartman and T. S. Chadwick. Private company.

TAYLOR & ROMANY (LTD.) (111,359).—Reg. Aug. 17, capital £2,000 in £1 shares, to take over the business of ironmongers and locksmiths, bellhangers, electric, hydraulic and mechanical engineers, manufacturers of and dealers in electric, magnetic, telegraphic, telephonic and other appliances, carried on as Taylor & Romany. NOTES.

The British Association.

THIS year the British Association meets at Sheffield, and everything points to a successful gathering. On Wednesday evening the Rev. Prof. T. G. BONNEY delivered his presidential address before a crowded and brilliant audience, and yesterday the presidents of the various sections delivered their addresses. At the time of going to press the official number of persons attending this year's meeting was 1,400. An attractive programme of social events has been arranged, and it would appear that Sheffield is determined to maintain its ancient reputation for hospitality to strangers within its gates.

PROF. DALBY'S presidential address to Section G was of the ideal British Association type. It dealt with an extremely interesting and difficult subject in a manner capable of being understood by the veriest amateur. Statistics relating to railways always claim the attention of the intelligent public, but they are rendered positively thrilling when they are accompanied by reliable data furnished by a distinguished engineer. The burden of Prof. DALBY'S song is that electric traction is the only thing for services involving frequent starts and stops; but he goes further than this and says that the London, Brighton & South Coast Railway Co.'s so-called "experiment" contains the germs of practicable long-distance electrification. It is almost to be regretted that he did not dwell rather more fully on this part of the subject but we may hope that he will have more to say after Mr. PHILIP DAWSON has read his Paper.

Municipal Wiring Powers.

IT will be remembered that a clause conferring powers on municipal authorities to do wiring and to supply electrical fittings on hire within their areas was inserted in the Electric Lighting Bill of 1909. This clause was so amended in the House of Lords as to make it unacceptable to municipal electrical engineers, and it was, therefore, deleted from the Bill. The Incorporated Municipal Electrical Association, who discussed the subject at their annual convention in Glasgow, recently sent out a communication to the various local authorities to discover whether sufficient support would be forthcoming should a Bill be introduced to confer, among other things, powers for wiring and hiring on such local authorities as possess electricity supply undertakings. The results of this canvass will be found on another page of this issue, from which it will be seen that a large majority of those who replied are in favour of the proposal, and even go so far as to promise financial support. We may, therefore, presume that the Municipal Electrical Association will introduce a Bill in the next Parliamentary Session to obtain the powers they require, and we may certainly prophesy that their proposals will meet with opposition. It is well that this should be so. We have no objection to municipalities wiring or hiring where no contractors are available to do the work or where the contractors are supine and do not appreciate what is required of them. But we do not approve of a municipality becoming a trading concern and entering into destructive competition with those who help to provide its sinews of war. Unfortunately this course is occasionally adopted by some municipalities who already possess the powers which the proposed Bill would confer on all. In view of the necessity for those supplying electricity being

Digitized by Google

in a position to develop their undertakings on modern business lines we think that a well-planned scheme of letting motors and heating and cooking apparatus on hire would be of great advantage to them. As, however, there appears to be a conflict of interests between the supply authorities and the contractors, we hope that the subject will be fully discussed in all its aspects and a compromise reached.

Breakdowns of Machinery.

THE annual report of Mr. M. LONGRIDGE, chief engineer to the British Engine, Boiler & Electrical Insurance Co., always provides interesting reading, on account of the valuable information and hints that it contains. The report for the year 1909, of which an abstract will be found elsewhere in this issue, is no exception to the general rule. On the present occasion less space is devoted to the customary descriptions of typical breakdowns, which latter have proved of smaller interest than usual; but this has allowed particulars of some interesting tests carried out by the engineers of the Company to be included with the report. The rate of breakdown among both steam engines and gas engines is about the average for the last few years, the figures being 1 in 10·2 and 1 in 10·4 respectively for the two types of engine. At present only comparatively few steam turbines are insured, but in a year or two, doubtless, some valuable information as to their reliability compared with reciprocating engines should be available. It is interesting to notice Mr. LONGRIDGE'S observations on the improvement in British methods of design brought about by technical education and foreign competition. In this connection the design of gas and oil engines is apparently inferior to that of steam engines, crankshafts in particular showing an increased tendency to failure, as is clearly indicated by the fact that, whereas for the six years previous to 1908 the percentage of breakdowns due to failure of crankshafts was 5·0, this figure had increased to 9·1 in 1908 and to 13·4 in the past year. The producer also seems a weak point in gas plants, the percentage of failures showing a marked increase.

TURNING now to electrical machinery, it is very gratifying to observe evidence of greater reliability, as indicated by the fact that the percentage of breakdowns of dynamos has decreased by 2·2 per cent., of motors by 6·2 per cent., and of starting switches and controllers by 7·5 per cent. It is to be noted, however, that bad workmanship or defective design accounts for a greater proportion of failures in all electrical apparatus than a year ago, whilst age and deterioration have become a much less frequent cause of trouble, probably largely owing to the inspection carried out by the Company. One of the most striking testimonies in favour of electrical machinery is the fact that only 1 per cent. of the breakdowns has been due to overloading. In view of the small indication given by electrical apparatus when subjected to an overload and the frequent placing of such apparatus under the control of unskilled workmen, such a record is certainly noteworthy.

Tramway Brakes.

THE question as to which is the most satisfactory brake for an electric tramcar has received considerable attention during the last few years both in this country and abroad; but although valuable contributions to this subject have been made, substantial difference of opinion still exists. It is interesting to note that in New Zealand this question has been deemed worthy of the attention of a Royal Commission. This Commission, which was appointed to report upon the most suitable form of brake for the Auckland (N.Z.) electric tramways and also to consider generally the question of tramway efficiency and safety, has recently sent in its report to the Government. It recommends that the Auckland Tramway Co. be requested to fit its cars with an approved type of pneumatic wheel brake and pneumatic sanding gear and to reconstruct the existing track brakes so that it may be possible to transfer 45 per cent. of the weight of a loaded car to the slipper blocks. The pneumatic brake was favoured by the Commission on account of its reliability, independence of track equipment, smoothness of working, efficiency at all attainable speeds, and ease of installation compared with that of the magnetic brake, which is stated to be unsuitable for the existing equipment of the Auckland cars. It appears, however, that the latest forms of magnetic brake have not yet been tested in the Dominion. Although adopted to no small extent abroad, the pneumatic wheel brake for tramcars has not found favour in this country; but that it is worth consideration is shown by the fact that, in their 1908 report on brakes, the Committee of the Light Railways and Tramways Association suggested that more attention might be paid to air brakes.

Brussels Exhibition Fire.

As may be seen on reference to our correspondence columns, the rumour that the Brussels fire originated from defective electrical apparatus has been officially contradicted. In support of the statement, it is pointed out that all electrical supply had been cut off for several hours from the buildings where the outbreak commenced. Clearly, this gives the *coup de grâce* to the "fusing of an electric wire" theory. Fortunately, the daily papers are becoming more cautious about alleged electrical fires, and this is only as it should be. If, however, they are really beginning to see the futility of their policy for the last few years, it now remains with them to make amends by giving as much publicity as possible to statements of fact issued by responsible persons. Meantime the Board of Trade Exhibitions Department is making most satisfactory progress with the new British section. Mr. WINTOUR, the Commissioner-General, states that applications for space in the Salle des Fêtes have been so numerous and spontaneous that personal negotiations have been unnecessary. The electrical exhibitors have responded promptly to the call for a representative display in the remodelled section, and practically all the firms formerly showing have got their new exhibits together. The firms include Messrs. Kelvin & James White, Nalder Bros. & Thompson, R. W. Paul, Cambridge Scientific Instrument Co., and Gambrell Bros., who are to be complimented on the enterprising manner in which they have reconstructed their exhibits.

Engineering Standards Committee.—We have received from this committee a copy of the revised edition of the specification for Portland cement. On account of the difference

Digitized by Google

found in the initial setting time when the British standard and Vicat needles were used, it was considered preferable that one instrument only should be specified for determining the initial and final setting and the Vicat needle has been adopted for this purpose. A minimum lime content has been inserted, with a view to excluding cements other than Portland cements; the total loss on ignition has been specified to provide an additional criterion of the quality of the cement and to restrict the amount of water present, and provision is now made for limiting the total amount of sulphur present in the cement, whether in the form of sulphides or sulphates.

Remarkable Performance of an Induction Motor.—According to "Engineering News" the behaviour of apparatus under exceptional circumstances reveals the weak or strong points in its design and determines whether it is suitable to perform the service for which it has been installed. A 20 H.P. three-phase 220-volt standard induction motor recently demonstrated its ability to operate successfully under the trying conditions met with in mines where the air is unusually damp. The motor was only partly enclosed; this is important, for thorough ventilation of the motor is absolutely necessary in mines where high temperatures prevail. The motor in question was geared to a mine pump located at the bottom of a shaft on the mines of the Richmond Iron Works. Surface water broke into one of the upper levels and flooded the mine. The water rose so rapidly that the electric pump and motor were soon 2 ft. below the level of the water. Under such circumstances it was imperative that the pump should continue in operation. At the end of two hours, during the whole of which time the motor was submerged, it had pumped itself clear and was then stopped long enough to clean the dirt and chips from the rotor and to put oil in the bearings. It was re-started immediately. The pump has been running about 20 hours a day ever since, and the motor apparently suffered no injury from its unusual experience.

Electric Locomotives on Steep Gradients.—The "Engineering and Mining Journal" describes an installation at Holt & Gregg's lime quarry at Kennet, California, as an example of the operation of electrical apparatus under heavy conditions. This quarry is near the copper mines and smelting works of the Mammoth Copper Mining Co., and supplies the limestone flux. The quarry is 2 miles from the station where the rock is stored for the smelting company, and about 2,000 ft. above the ore bins. In order to transport the rock to this point a road was built round two mountains, necessitating many curves and heavy gradients. There are 35 curves, with radii varying from 35 ft. to 55 ft. The entire road has heavy gradients, varying from 4 to 12 per cent., the average being about 7 per cent. This road was originally laid out as a wagon road, but was afterward changed into a 30 in. gauge mule tramway, equipped with 30 lb. rails. The demand for limestone became so great that it was not possible to supply it with this equipment. An electric locomotive was purchased and a new system put into operation. The locomotive handles three-car trains, each car weighing 4,400 lb. empty. The wooden body is mounted on substantial double trucks, having a 3 ft. wheel base. A complete braking equipment was provided, consisting of both track and wheel brakes. The locomotive had a rating of 11 tons, and was equipped with two 42 H.P. 550-volt motors. On account of the heavy gradients and consequent wear of the wheels by the brakes, the locomotives were equipped with track brakes in addition to the standard wheel brakes. Three locomotives are in use and a switching system has been installed, so that two locomotives can travel back and forth, each making about 10 trips during the day. Owing to the mountainous country, it was necessary to instal the power station at the end of the line.

A.C. Motors in New Axle Mill at Gary.—The "Electrical World" states that, following the practice initiated with the design of the new 14 in. and 18 in. merchant mills of the Indiana Steel Co. at Gary, Ind., which employ alternating-current motors throughout, the axle mill now nearing completion shares with them the distinction of having no direct-current lines entering the building except a single pair of wires conveying energy for the electric lifting magnets. These are used for lifting the steel billets from cars and placing them on the platforms of the re-heating furnaces. The main rolls are driven by a 500 H.P. 6,600-volt three-phase 25-cycle induction motor, running at 260 revs. per min., which is controlled from a contactor panel employing alternating-current auxiliary circuits of 220 volts. A number of 25 H.P. and 50 H.P. motors, used to control and raise the tables, conveying rolls, transfers, cut-off saws, &c., are also supplied from the 220-volt secondaries of the mill transformers, a transmission voltage of 6,600 being employed about the plant. At the Gary axle mill the process of shaping the axles by the rolls is carried further than at any other plant, requiring less subsequent work in finishing the axles by means of the steam hammers. In the rolls each billet is reduced to practically a round section twice the length of a car axle. Heretofore it has been the practice to attempt only a rough shaping by the rolls. All the crane and hoist motors in this mill are of the alternating-current type.

The Scattering of Homogeneous β-Rays and the Number of Electrons in the Atom.—In a Paper on this subject read recently before the Royal Society, Mr. J. A. Crowther showed that the scattering of a homogeneous pencil of β-rays had been measured for various substances and for rays of different velocity. It had been shown to obey the following laws: For rays of given velocity the intensity I of the radiation contained within a given cone may be expressed by the equation $I/I_0 = 1 - e^{-kt}$, where t is the thickness of material and k a constant depending upon the angle of the cone. For rays of given velocity the most probable angle of emergency was proportional to the square root of the thickness of material traversed by the rays. For rays of different velocities the probable angle of emergence divided by the square root of the thickness traversed was inversely proportional to the product of the mass of the incident β-particle into the square of its velocity. From equations given by Sir J. J. Thomson the number of electrons contained in atoms of different elements was deduced. It was thus found: That the ratio of the number of electrons per atom to the atomic weight was constant, the ratio being very nearly 3·0 for all the elements examined; that the positive electricity within the atom was not in an electronic condition, but was distributed fairly uniformly over the space occupied by the atom. Experiments were also described on the absorption of homogeneous β-rays. It was shown that the first stage in the absorption of a pencil of homogeneous β-rays consisted in the scattering of the rays according to the laws already considered. The absorption of the completely scattered radiation was then shown to take place according to an exponential law.

New Telephone Exchange at Willesden.—A new telephone exchange will be opened on Saturday next by the Post Office in the metropolitan area at Willesden. Its present capacity is 2,700 lines, with facilities for an increase to 8,100 lines. The general equipment, which has been provided by the Peel Conner Telephone Works (Ltd.), is on exactly similar lines to that of the new Glasgow telephone exchange, which we have recently described. It is interesting to note that the exchange is the first in the London area to employ a 40-volt common battery, as distinct from the more usual 22-volt battery. Provision has been made for 208 incoming junctions, 240 outgoing junctions and 40 incoming order wires. The subscribers' board is divided into six eight-panel sections with nine-panel multiples, there being three operator's positions for each section. All the cables which enter the exchange are underground, and are brought into the building by way of the basement, where the junctions between the paper insulated and the silk and cotton cables are made in the usual way. The bulk of the equipment is on the ground floor, and includes

Digitized by Google

the main frame, intermediate distribution frames, wire chief's desk, and relay and condenser racks. The power plant, which has been provided by the General Electric Co., is on the same floor, together with a battery of E.P.S. cells. The switch-room is on the first floor where ample provision for natural lighting is made.

Electric Shock.—At the recent meeting of the British Medical Association Dr. S. Jellinek, of Vienna, read a Paper on "Disorders and Death following Electric Shock." He said that, while in some cases fatal accidents had been brought about by shocks at 100 volts, in other cases, in which the voltage had been 1,000, and even 10,000, recovery had ensued. In order to understand a matter so seemingly inconsistent, it should be kept in mind that the danger of an electric current depended on circumstances which might be placed in the following two categories: 1. The external: (*a*) voltage, (*b*) amperage, (*c*) number of poles, (*d*) the time of contact, and (*e*) the kind of current (continuous or alternating). The continuous current appeared to be more dangerous than the alternating. 2. The individual: (*a*) the resistance of skin and body, (*b*) the way, or the path, of the current through the body and over the surface of the skin, and (*c*) the condition of mind and body. With regard to section (*a*) of the second category, the resistance of the skin played a very important rôle, and not only the resistance of entrance, but also that of exit for the current. As to section (*b*), Dr. Jellinek said that the failure of American electrocution was most probably due to causes connected with the management of the poles, which were much moistened, a great part of the current passing over the surface of the skin, and thus not coming in contact with the organs of sensibility—the brain, the heart, &c. Under section (*c*) there was, he said, an enormous difference between the touching of a current intentionally (the mind being prepared and ready for the shock) and doing it accidentally, in the latter case the shock being liable to produce an inhibition of the functions of important organs. Electricity which passed into the body had, he said, two actions—a psychological action and a material actiont on the cells of the brain through the microscopical vessels of the brain, the spinal cord, the heart, &c. The result of both these actions might be either disease or death. The clinical symptoms emanated from various organs—unconsciousness, spasm, paralysis, hæmorrhage of the kidneys, degeneration of nerves, &c. The alteration of the skin (local lesions) sometimes took the form of genuine burnings and sometimes of so-called specific electric changes, which pathologically and clinically were quite different in character from other wounds. It was important to know that genuine electric lesions were painless. With regard to the mechanism of death by electricity there was no definite scheme or model. In most cases it seemed like suspended animation. It was an interesting fact that there was between electric shock and death an interim of a few seconds in which the stricken person appeared to be in quite a normal state. By experiments on dogs in the physiological institute of Prof. von Tschermak it had been discovered that the irritability of the brain, which had subsided immediately after a shock, had a few seconds later become re-established, and everything then depended upon whether the action of the heart would be continued or not. As there were sometimes hæmorrhages in the brain, and as the pressure of the cerebro-spinal liquid was increased, it was necessary and important in cases of first aid to lay the patient with the head elevated.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. W. H. Eccles contributes an article on "Recent Patents in Wireless Telegraphy."

We conclude our description of the new Post Office telephone exchange at Glasgow.

Mr. D. Owen contributes an article on "Rutherford's Work on the α-Particle."

At the meeting of the British Association at Sheffield yesterday the presidential addresses to the various sections were delivered. We give an abstract of Prof. W. E. Dalby's address to Section G (Engineering) and of Prof. E. W. Hobson's address to Section A (Mathematical and Physical Science).

Mr. M. Longridge, chief engineer of the British Engine, Boiler & Electrical Insurance Co., has issued his annual report dealing with the breakdowns of machinery. Considerable improvement is recorded in the reliability of electrical apparatus.

In our correspondence columns Mr. P. A. Mossay describes a new system of railless traction.

Sir Joseph Ward, Prime Minister of New Zealand, recently announced that it was the intention of the Government to control the whole of the powers for utilising water power throughout New Zealand.

An interesting consular report on how to develop trade with Russia is abstracted in another column.

It is evident that the recent fire at the Brussels Exhibition was not caused electrically, since the electrical supply in the buildings where the fire started had been cut off for some hours previous to the outbreak.

We analyse the accounts for the year ended March 31 last of the Bolton Corporation electricity department.

Particulars of an important Indian hydro-electric scheme are given on another page.

Brighton Council are recommended to renew the piping of the condenser circulating system at Southwick electricity works, at a cost of about £1,800. This renewal is necessitated by mussel spawn and other marine growths having got through the strainer and attached themselves to the inner surfaces of the pipes. The timber piling of the wharf is also to be replaced by reinforced concrete.

Bradford Tramways Committee have appointed a sub-committee to superintend the construction of a route on the railless trolley system.

Plymouth Tramways committee are considering a report on the advisability of equipping a route on the railless trolley system.

An abstract of the report of the New Zealand Post and Telegraph Department for 1909-10 appears in another column.

An interesting report is issued by Glasgow Electricity Department on the result of the past year's operations to May 31st. A surplus of £191 compares with a deficit last year of £3,545.

Loans for Electricity Undertakings.—Bispham Council have applied for sanction to a loan of £9,855 for electricity supply.

Companies' Meetings and Reports.—At the meeting of the Mersey Railway Co. last week the chairman announced that the electrification of their line had enabled them to increase the number of passengers carried by 120 per cent. and the receipts by 85 per cent. The line was making steady progress.

INSTITUTIONS AND SOCIETIES.

University of Sheffield.—On the occasion of the meeting of the British Association a special degree congregation of the University will be held at which the following honorary degrees will be conferred:

Doctor of Science.—Mr. W. Bateson, F.R.S., the Rev. Prof. T. G. Bonney, F.R.S., Sir W. Crookes, F.R.S., Mr. F. Darwin, F.R.S., Prof. T. W. Rhys Davids, Sir A. Geikie, P.R.S., Prof. E. W. Hobson, F.R.S., Sir O. Lodge, F.R.S., Sir N. Lockyer, F.R.S., Dr. H. A. Miers, F.R.S., Sir W. Ramsay, F.R.S., Prof. C. S. Sherrington, F.R.S., and Sir J. J. Thomson, F.R.S.

Doctor of Engineering.—Sir J. Jonas, Sir W. H. White, F.R.S.

Doctor of Metallurgy.—Mr. J. E. Stead, F.R.S.

Doctor of Laws.—The Lord Mayor of Sheffield (Lord Fitzwilliam).

Tramways and Light Railways Association.—The "Official Circular" of this Association for August contains a reproduction of the settlement arrived at with the Board of Inland Revenue in 1909 in regard to allowances for depreciation for assessment of income tax, an official list of the returns available in regard to the exercise of the powers conferred by light railway orders since the passing of the act of 1896, and a list of the results obtained in regard to bills relating to tramways promoted during the current year.

Municipal Tramways Association.—The annual conference of this Association will take place at Bradford from September 21st to 23rd.

ARRANGEMENTS FOR THE WEEK.

BRITISH ASSOCIATION.

FRIDAY, September 2nd (To-day) to WEDNESDAY, September 7th.
Meeting at Sheffield.

BOLTON CORPORATION ELECTRICITY SUPPLY ACCOUNTS.

In analysing the accounts of the Bolton Corporation electricity department a year ago we had to record a set-back in the output of electrical energy. This decrease was due to trade depression and the use of metal filament lamps, the sales of energy for both lighting and power being smaller than in the previous year. On the present occasion, however, we are pleased to see that the steady expansion which has usually marked this undertaking has been resumed, the number of units sold during the year ended March 31, 1910, amounting to 11,993,271, compared with 10,677,764 last year and 10,791,105 in 1907-8. The most satisfactory feature of the expansion is that an increase is recorded in the sales of energy for all purposes; thus, private lighting shows an increase of 3·6 per cent., power 22 per cent. and traction 4·1 per cent.

The Bolton electricity undertaking has of recent years been noteworthy for its low costs of generation and its low charges for power supply. A large proportion, moreover, of the output of the undertaking now goes to meet the requirements of power users, 6,013,928 units, or over 50 per cent. of the total output, being sold for private motors and 4,352,208 units, or 36 per cent., to the tramway department. When it is mentioned that the average price received from power users was only 0·812d. per unit (0·85d. a year ago), whilst lighting consumers obtained their energy at an average price of 2·75d. per unit (2·81d. a year ago), it is evident that cheap power supply by no means implies penalising lighting and other consumers. It is noteworthy that, although the average price received for the total output was only 1·18d. per unit (after deducting discounts), a sum of £6,500 was handed over to the district funds in aid of the rates, after £4,664 had been set aside for renewals.

It need scarcely be remarked that such a result is only possible by careful attention to the cost of generation and distribution and to capital expenditure. As will be seen from our analysis of the accounts below, the total costs (excluding capital charges) were 0·56d. per unit, whilst capital charges amounted to 0·46d. per unit, the inclusive cost, therefore, being 1·02d., as against 1·07d. last year.

In regard to the growth of the undertaking, 185 new consumers were connected to the mains during the past 12 months, bringing the total number of consumers to 2,628. The motor load has increased during the same period by about 800 H.P., representing 99 motors installed by 25 new consumers. The total power load on March 31st last was 915 motors of 10,017 H.P. aggregate. The length of mains laid has also been increased by 9,700 yds. during the year, so that the department has been by no means inactive.

We notice that the number of units unaccounted for has considerably increased—viz., 1,288,851 units, as against 977,045 last year. This represents for the year ended March 31st last 9·04 per cent. of the total energy generated, compared with 7·85 per cent. in 1908-9 and 7·33 per cent. in 1907-8.

The plant capacity remains unchanged—viz., 7,600 kw.—the maximum load recorded during 1909-10 being 5,941 kw., compared with 4,925 kw. in the year 1908-9. The load factor continues to decrease, being now only 23·1 per cent., as against 24·75 per cent. a year ago and 27·35 per cent. in 1907-8.

We give below an analysis of the expenditure and revenue for the year ended March 31st last, together with the cost per unit sold, the latter figure for the year 1908-9 being given for the sake of comparison.

Generating Costs.		Cost per unit sold. 1909-10.	1908-9.
Fuel	£12,500	0·25d.	0·26d.
Oil, waste, stores, &c.	990	0·02d.	0·02d.
Salaries and wages at station	3,549	0·07d.	0·08d.
Repairs and maintenance	3,753	0·08d.	0·09d.
Total Generating Costs	£20,792	0·42d.	0·45d.
Distribution Costs.			
Wages	£352	0·01d.	0·03d.
Repairs and maintenance of mains, meters, motors, &c.	693	0·01d.	
Meters and motors purchased out of revenue	1,335	0·03d.	
Total Distribution Costs	£2,380	0·05d.	0·03d.
Management Costs			
Salaries	£1,292	0·03d.	0·03d.
Printing, stationery, &c.	96	0·00d.	0·00d.
Insurances	54	0·00d.	0·00d.
Miscellaneous	331	0·00d.	0·01d.
Total Management Costs	£1,773	0·03d.	0·04d.
Rents, rates and taxes	£3,140	0·06d.	0·07d.
TOTAL COSTS (ex capital charges)	£28,085	0·56d.	0·59d.
Capital Charges.			
Interest	£8,563	0·17d.	0·19d.
Sinking fund	14,584	0·29d.	0·29d.
Total Capital Charges	£23,147	0·46d.	0·48d.
TOTAL COSTS (inc. capital charges)	**£51,232**	**1·02d.**	**1·07d.**
Depreciation	4,664	0·09d.	0·13d
Special, written off mains	356	0·01d.	—
Work executed for customers and goods for sale	11,888	0·24d.	0·14d.
TOTAL EXPENDITURE	**£68,140**	**1·36d.**	**1·34d.**
Revenue.			
Sale of current	£62,730	1·25d.	1·33d.
Meter and motor rentals	1,604	0·03d.	0·03d.
Work executed for customers and goods sold	13,051	0·26d.	0·20d.
Less discounts, &c.	3,806	0·07d.	0·09d.
TOTAL REVENUE	**£73,579**	**1·47d.**	**1·47d.**
Balance	£5,439	0·11d.	0·13d.

To this balance of £5,439 is added £2,680 brought forward from April 1, 1909, making a total of £8,119, from which £1,000 is written off for the Duncan-street sub-station, £6,500 handed over to the relief of the rates, and the balance of £619 carried forward to next year's accounts.

During the 12 months the capital expenditure has been augmented by £8,110, and now amounts to £359,690. In the following table we give the total amounts expended on the various sections of the plant, together with the cost per kilowatt installed.

	Total.	Per kw. installed.
Land	£4,709	£0·6
Buildings	46,628	6·1
Machinery	148,396	19·5
Mains	109,505	14·4
Motors	13,428	1·8
Transformers	9,305	1·2
Meters	13,747	1·8
Instruments	443	0·1
Well sinking	2,124	0·3
	£348,285	£45·8

PROF. DALBY'S ADDRESS TO SECTION G OF THE BRITISH ASSOCIATION.*

The author calls attention to the large part that railways play in our national life, and figures and curves are given to show the development in capital, length of track, number of passengers carried, &c., between the years 1850 and 1909. In 1908 the total paid-up capital was 1,310 millions sterling, 38 per cent. of this being ordinary stock. Gross receipts were 120 millions of pounds and net revenue 43½ millions. At the end of 1908 there were 23,205 miles of line open, corresponding to 53,669 miles of single track, including sidings. Of this, 85 per cent. was standard 4 ft. 8½ in. gauge, 12·3 per cent. 5 ft. 3 in., and 2·2 per cent. 3 ft. gauge. The remainder was made up of small mileages of 1 ft. 11½ in., 2 ft. 3 in., 2 ft. 4 in., 2 ft. 4½ in., 2 ft., 2 ft. 9 in., 4 ft. and 4 ft. 6 in. gauges.

* Abstract of the Presidential Address delivered by Prof. W. E. Dalby, M.A., at Sheffield yesterday.

Digitized by Google

Curves showing mileage, passengers carried and goods carried increase regularly with the increase of capital, indicating that up to the present time the possibility of remunerative return on capital invested in railway enterprise in this country is not exhausted. In 1908 the railways of the United Kingdom carried 1,278 millions of passengers, exclusive of season-ticket holders, and 491 million tons of goods. It is curious that very approximately the companies carry per annum one passenger and about 0·4 ton of goods for every pound sterling of paid-up capital.

Fig. 1 indicates the cost of working the traffic calculated in terms of the train-mile, no data being available regarding the actual work done as represented by the ton-mile or the passenger-mile. In some respects the train-mile is the fairest way of comparing costs, because when a train is running, whether it is full or empty, the same service must be performed by the majority of the departments. The curves bring out clearly that the proportion of the total expenditure per train-mile absorbed by these several services remains fairly constant over a series of years. To the right is exhibited the average for the four years 1905 to 1908. Locomotive power absorbs an amount about equal to the traffic expenses; and companies actually pay in rates and taxes a sum nearly equal to the whole amount required to maintain the rolling-stock in an efficient state. To the right is shown a scale the divisions of which represent an amount estimated in pence per train-mile corresponding to 1 per cent. of the average dividend. This shows that if the whole of the locomotive power could be obtained for nothing, the average dividend would only be increased

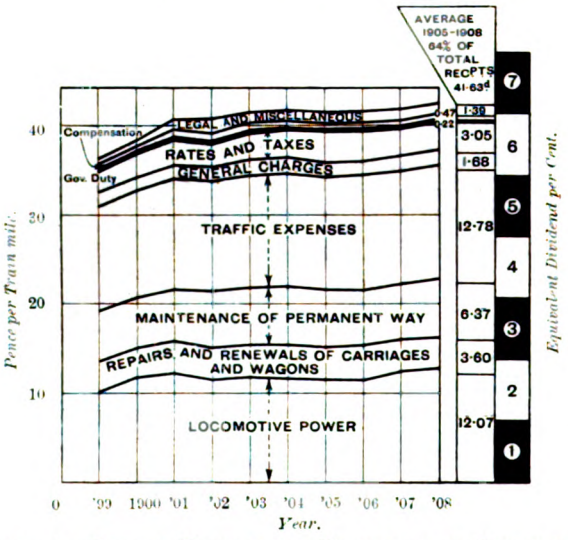

FIG. 1.—COST OF WORKING PER TRAIN-MILE OF RAILWAYS IN ENGLAND AND WALES.

by 1¾ per cent. Reckoned on the ordinary stock alone, however, the increase would be about three times this amount.

The author next compares the financial position and the cost of the working of railways in their earlier days with the state of things now. For this purpose the position of the old London & Birmingham Railway is compared with the position of the London & North Western Railway, the system into which it has grown. The years selected are 1840 and 1908. The comparison brings out some curious facts. For instance, the gross receipts of the London & North Western Railway in 1908 were 22½ times as much as those of the London & Birmingham Railway in 1840, and the track mileage open was about 22 times as great. The money earned per mile of track open is thus practically the same after a lapse of 70 years. To earn the same amount per mile of track open, however, the trains of the London & North Western Railway had in 1908 to run 68·3 times the number of train-miles that the trains of the London & Birmingham Railway ran in 1840. That is to say, in order to earn a sovereign a London & North Western train has now to run three times the distance which it was necessary for a London & Birmingham train to run to earn the same amount.

Another point to notice is that although the mileage and the receipts per mile of track open have each increased in the same proportion, yet the capital has increased at a greater rate, being on the total amount 24 times as much as in 1840, and the stock and share capital has increased 28 times. So that with the necessity of running three times the train-mileage to obtain the same return per mile of track open there is the obligation to pay interest on an ordinary stock which has been increased in a greater proportion than the mileage and in a greater proportion than the earning power of the line. Lower dividends are, therefore, inevitable. The cost of working per train-mile has decreased gradually to about half its value in 1840, but at the same time the receipts per train-mile have dwindled to one-third of the amount in 1840. These figures show that a more conservative system of financing the railways might have been adopted in the earlier days with advantage. If when the receipts per train-mile were larger, a proportion of the revenue had been used annually for the construction of new works and for the provision of new rolling-stock instead of raising fresh capital for everything in the nature of an addition to the railway, the companies would to-day have been in a position to regard with equanimity the increasing cost of working. It is too late in the day to recover such a strong financial position, but even now on many lines a larger proportion of the revenue could be sunk in the line with great ultimate advantage to the financial position.

Locomotive Problems.—During the last 20 years the demand on the locomotive has steadily increased. The demand has been met, though with increasing difficulty, owing to the constructive limitations imposed by the gauge. An accurate estimate of the rate at which work must be done to run a stated service can only be made if there are given the weight of the vehicles in the train, the weight of the engine, the kind of stock composing the train, the speed and acceleration required at each point of the journey and a section of the road; and, in addition to this, allowance must be made for weather conditions.

A general idea of the problem can, however, be obtained by omitting the consideration of acceleration, gradients and the unknown factor of weather conditions, considering only the rate at which work

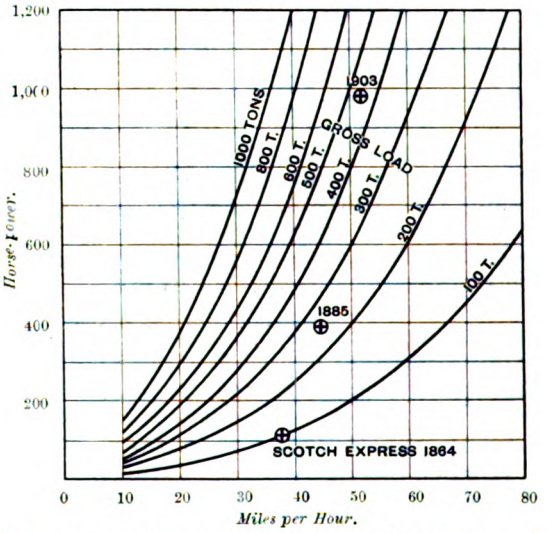

FIG. 2.—POWER REQUIRED TO MAINTAIN SPEED ON THE LEVEL.

must be done to draw a given load at a given speed on the level. Even thus simplified the problem can be solved only approximately because, although the tractive resistance of a train as a whole is a function of the speed, the tractive resistance per ton of load of the vehicles and per ton of load of the engine differ both in absolute value and in their rates of change for a stated speed, and, further, the ratio between the weight of the vehicles and the weight of the engine is a very variable quantity. For our purpose, however, it will be sufficiently accurate to assume that the resistance of the whole train, expressed in pounds per ton, is given by the formula $T = 5\frac{1}{3} + V^2/256$. It follows that the horse-power which must be developed at the driving-wheels to maintain a speed of V miles per hour on the level with a train weighing W tons is

$$HP = W\left(\frac{V}{70} + \frac{V^3}{96{,}000}\right).$$

Fig. 2 shows curves of horse-power plotted from this equation for various weights of trains. From this diagram a glimpse of the problem confronting locomotive engineers at the present day can readily be obtained. To illustrate the point, consider the case of the Scotch express on the West Coast route. Three specific examples are plotted on the diagram, showing the power requirements in 1864, 1885 and 1903 for this train. Typical trains in 1864, 1885 and 1903 weighed, including engine and tender, 100 tons, 250 tons and 450 tons respectively. The average speeds were 38, 45 and 52 miles per hour respectively. A glance at the diagram will show that the power required to work this train was about 100 H.P. in 1864, 400 H.P. in 1885 and 1,000 H.P. in 1903. Moreover, the increase in the weight of the train does not mean a proportionate increase in the paying load. Far from it. In 1903 an average of 1·4 tons of dead load had to be hauled

Digitized by Google

by the engine per passenger, assuming the train to be full. In the days before corridor stock and dining cars were invented the dead load to be hauled was about a quarter of a ton per passenger for a full train. Notwithstanding the increase in the dead load of luxurious accommodation, the fares are now less than in former days on corresponding services. Similar developments have taken place in almost every important service, and new express services are all characterised by heavy trains and high speeds.

Characteristic Energy-curves of Steam Locomotives.—This steadily increasing demand for power necessarily directs attention to the problem, What is the maximum power which can be obtained from a locomotive within the limits of the construction-gauge obtaining on British railways? The answer to this can be found without much ambiguity from a diagram which I have devised consisting of a set of typical characteristic energy-curves to represent the transference and transformation of energy in a steam locomotive, an example of which is given in Fig. 3. While examining the records of a large number of locomotive trials, I discovered that if the indicated horse-power be plotted against the rate at which heat energy is transferred across the boiler-heating surface the points fall within a straight line region, providing that the regulator is always full open and that the power is regulated by means of the reversing-lever, that is to say, by varying the cut-off in the cylinders. It is assumed at the same time, of course, that the boiler-pressure is maintained constant.

In Fig. 3 the horizontal scale represents the number of British thermal units transferred across the boiler-heating surface per minute. This quantity is used as an independent variable. Plotted

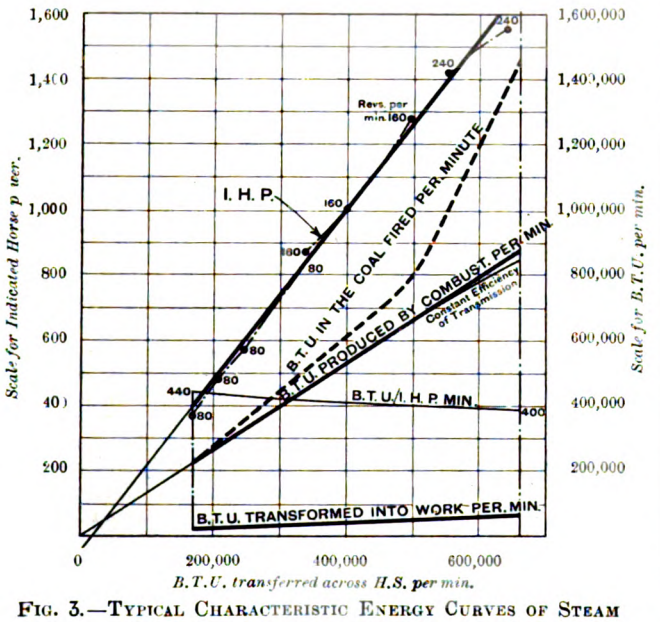

FIG. 3.—TYPICAL CHARACTERISTIC ENERGY CURVES OF STEAM LOCOMOTIVES.

vertically are corresponding horse-powers, each experiment being shown by a black dot on the diagram. The small figures against the dots denote the speed in revolutions of the crank-axle per minute. Experiments at the same speed are linked by a faint chain dotted line. A glance at the diagram will show at once how nearly all the experiments fall on a straight line, notwithstanding the wide range of speed and power.

The ordinates of the dotted curve just below the indicated-horse-power curve represent the heat energy in the coal shovelled per minute into the fire-box—that is, the rate at which energy is supplied to the locomotive. The thick line immediately beneath it represents the energy produced by combustion. The vertical distance between these two curves represents energy unproduced, but energy which might have been produced under more favourable conditions of combustion. Some of the unproduced energy passes out of the chimney-top in carbon monoxide gas, but the greater portion is found in the partially consumed particles of fuel thrown out at the chimney-top in consequence of the fierce draught which must be used to burn the coal in sufficient quantity to produce energy at the rate required. The rate of combustion is measured by the number of pounds of fuel burnt per square foot of grate per hour. In land practice with natural draft 20 lb. of coal per square foot of grate per hour is a maximum rate. In a locomotive the rate sometimes reaches 150 lb. per square foot per hour. In the diagram shown the maximum rate is about 120 lb. per square foot, and the dotted curve begins to turn upwards at about 70 lb. per square foot per hour. The vertical distance between the curves shows what has to be paid for high rates of combustion.

I found that in almost every case the curve representing the energy actually produced by combustion differed very little from a straight line, passing through the origin, showing that at all rates of working the efficiency of transmission is approximately constant. That is to say, the proportion of the heat energy actually produced by combustion in the fire-box which passes across the boiler-heating surface per minute is nearly constant and is therefore independent of the rate of working. The lowest curve on the diagram represents the rate at which heat energy is transformed into mechanical energy in the cylinders of the locomotive. It seems a small rate in proportion to the rate at which heat energy is supplied to the fire-box, but it is not really so bad as it looks, because the engine actually transformed 60 per cent. of the energy which would have been transformed by a perfect engine working on the Rankine cycle between the same limits of pressure. The engine efficiency is represented in a familiar way by a curve labelled "B.T.H. per indicated-horse-power minute." It will be seen that the change of efficiency is small, notwithstanding large changes in the indicated horse-power.

The diagram indicates that the indicated-horse-power is practically proportional to the rate at which heat is transferred across the boiler heating surface, and as this is again proportional to the extent of the heating-surface, the limit of economical power is reached when the dimensions of the boiler have reached the limits of the construction-gauge, the boiler being provided with a fire-grate of such size that, at maximum rate of working, the rate of combustion falls between 70 lb. and 100 lb. of coal per square foot of grate per hour. A boiler of large heating-surface may be made with a small grate necessitating a high rate of combustion to obtain the required rate of heat-production. Then, although a large power may be obtained, it will not be obtained economically.

Returning now to the consideration of the type of locomotive required for a local service with frequent stops, the problem is to provide an engine which will get into its stride in the least time consistent with the comfort of the passengers. The average speed of a locomotive on local service is low. The greater part of the time is occupied in reaching the journey speed, and the brake must then often be applied for a stop a few minutes after the speed has been attained. In some cases the stations are so close together that there is no period between acceleration and retardation. Without going into the details of the calculation I may say that to start from rest a train weighing, including the engine, 300 tons, and to attain a speed of 30 miles per hour in 30 seconds requires about 1,350 I.H.P. During the period of acceleration the engine must exert an average tractive pull of nearly 15 tons. Mr. James Holden, until recently locomotive engineer of the Great Eastern Railway, built an engine to produce an acceleration of 30 miles per hour in 30 seconds with a gross load of 300 tons. The engine weighed 78 tons and was supported on 10 coupled wheels each 4 ft. 6 in. diameter. There were three high-pressure cylinders, each 18½ in. diameter and 24 in. stroke. A boiler was provided with 3,000 sq. ft. of heating surface and a grate of 42 sq. ft. area. Boiler pressure, 200 lb. per square inch. This engine practically reached the limit of the construction-gauge.

An acceleration of 30 miles per hour in 30 seconds is considerably below what may be applied to a passenger without fear of complaint. But it is clear that it is just about as much as a locomotive can do with a train of reasonable weight. Even with a gross load of 300 tons nearly one-third of it is concentrated in the locomotive, leaving only 200 tons to carry paying load. The problem of quick acceleration cannot therefore be properly solved by means of a steam locomotive. But with electric traction the limitations imposed on the locomotive by the construction-gauge and by the strength of the permanent way are swept away. The equivalent of the boiler power of a dozen locomotives can be instantaneously applied to the wheels of the electric train, and every axle in the train may become a driving axle. Thus the whole weight of the stock, including the paying load, may be utilised for tractive purposes. The problem of quick acceleration is therefore completely solved by the electric motor.

Electric Railways.—December 18, 1890, is memorable in the history of railway enterprise in this country, for on that date the City & South London Railway was opened for traffic, and the trains were worked entirely by electricity, although the original intention was to use the endless cable system of haulage. Since that epoch-marking year electric traction on the railways of this country has made a gradual if somewhat slower extension than anticipated. But electrically operated trains have in one branch of railway working beaten the steam locomotive out of the field and now reign supreme—that is in cases, as indicated above, where a quick frequent serivce is required over a somewhat short length of road. The superiority of the motor over the steam locomotive, apart from questions of cleanliness, convenience and comfort, lies in the fact that more power

Digitized by Google

can be conveyed to the train and can be utilised by the motors for the purpose of acceleration than could possibly be supplied by the largest locomotive which could be constructed within the limits of the construction gauge. There are many other considerations, but this one is fundamental and determines the issue in many cases.

The author next gives a few statistics relating to the present state of electric railways in the United Kingdom, and refers to the "Tables of Electric Lighting, Power and Traction Undertakings of the United Kingdom" published annually by THE ELECTRICIAN.

The total number of passengers carried (exclusive of season tickets) on the 138 miles of electrical track during the year 1908 was nearly 342 millions, being roughly one-third of the total number of passengers carried on all the railways of England and Wales during the same period. The average cost of working this traffic is 22·3d. per train-mile. This figure includes the service of the lifts, which is presumably returned with the traffic expenses. The cost is made up as follows for the year 1908:—

	Pence per train-mile.
Locomotive power	8·40
Repairs and renewals of carriages and wagons	1·50
Maintenance of permanent way	2·40
Traffic expenses	5·22
General charges	1·52
Rates and taxes	2·36
Government duty	0·088
Compensation	0·116
Legal and miscellaneous	0·75
Total	22·35

The corresponding total receipts were 38·65d. per train-mile. The working expenses are thus 58 per cent. of the total receipts. Comparing this with the diagram given above for the whole of the lines in England and Wales, it will be seen that the cost for locomotive power on the electric railways appears to be about two-thirds of the cost on steam lines per mile run, the cost for repairs and renewals of carriages and wagons about one-half and the cost for traffic expenses about one-half. The two kinds of working are, however, not strictly comparable, as all the conditions of traffic in the two cases are different and the length of the electric lines is relatively so small that the problems which arise out of the transmission of electric power over long distances are excluded. The traffic expenses and the cost of repairs and renewals of carriages and wagons, general charges &c., are practically inedpendent of the kind of power used for locomotive purposes, and, moreover, the difference in weight of electric trains and the steam-hauled trains is on the average so great that no comparison can be instituted without ton-mile statistics.

With two exceptions the method of working the electrified lines of this country is in the main the same. A third conductor rail is laid on insulators fixed to the ordinary track sleepers, and is maintained throughout the whole of its length at as nearly as possible a pressure of 600 volts, except in a few cases where the pressure is 500 or 550 volts.

In 1908 the Midland Railway Co. opened for traffic the single-phase electrified line connecting Lancaster, Morecambe and Heysham, the method of electrification being a departure from the general practice hitherto applied to electrified lines in this country. The traffic conditions on this line are simple. In December, 1909, the electrified portion of the London, Brighton & South Coast Railway was opened for traffic. This work marks an epoch in the history of electric traction in England. For the first time the single-phase system was applied to meet the exacting traffic conditions of a London suburban service where the main condition is that the trains should be accelerated rapidly. The system has shown that it can meet all the conditions of the service perfectly. The results of this electrification will be of unusual interest because not only has the method applied shown itself to be quite suitable for dealing with a stopping traffic where quick acceleration is the dominating condition, but it contains the germ of practicable long-distance electrification. The near future may see the extension of the system to the line between London and Brighton, giving a frequent non-stop service which would bring Brighton in point of time nearer than the suburbs on opposite sides of London are to one another.

Power Signalling.—During the last 10 years a considerable number of trial installations of power-signalling apparatus have been made by the railway companies of this country. The electric lines have generally adopted power signalling, and the District Railway has installed a complete system on all its lines and branches. The term "power signalling" is applied to any equipment in which the actual movements of the points and signals are done by power, the signalman's work being thus reduced to the movement of small light control levers or switches. Of the several systems tried and proposed three bulk largest in the equipments applied in this country—namely, the all-electric, the low-pressure pneumatic and the electro-pneumatic systems.

The "all-electric" system is represented by installations of the McKenzie-Holland and Westinghouse system on the Metropolitan and Great Western Railways, by installations of the "Crewe" system on the London & North Western Railway, and by installations of Siemens Bros. on the Great Western Railway. The general feature of the all-electric system is that the points are operated by motors sunk in a pit by the side of the rails, the signals are pulled off electrically, and all the apparatus is controlled electrically.

The low-pressure pneumatic system is represented by installations on the London & South Western Railway and the Great Central Railway. The points and signal arms are moved by air compressed to about 20 lb. per square inch, and led to cylinders connected to the points and to the signal arms. The control is also done by means of compressed air, small pipes leading from each air-cylinder to the cabin.

The electro-pneumatic system has found most favour in this country up to the present time. The equipment installed includes such notable stations as the Central at Newcastle with 494 levers, and the Glasgow Central with 374 levers, and the whole of the Metropolitan District system of underground railways. In this system an air-cylinder is connected to each set of points and to each signal-arm. Air compressed to 65 lb. per square inch is supplied to the cylinders from a main running alongside the railway kept charged by small air-compressors placed at convenient intervals. Each air cylinder is provided with a small three-way air-valve operated by an electro-magnet. The movement of each air-valve is controlled electrically from the cabin through the electromagnet associated with it.

The obvious advantage of power signalling is the large reduction of physical labour required from the signalman. His energy can be utilised in thinking about the traffic movements rather than in hauling all day at signal levers. One man at a power frame can do the work of three at the ordinary frame. The claims made for power signalling in addition to the obvious advantage of the reduction of labour, are briefly that the volume of traffic which can be dealt with is largely increased, that the area of ground required for the installation is considerably less than with the ordinary system, with its rodding, bell-crank levers, chains and pulleys, and that where the conditions are such that power signalling is justified the maintenance cost is less than with a corresponding system of normal equipment.

Automatic Signalling.—Several of the power-signalling installations are automatic in the sense that between signal cabins on stretches of line where there are no junctions or cross-over roads requiring the movement of points, the movement of the signal-arm protecting a section is determined by the passage of the train itself. The most important equipment of this kind is that installed on the group of railways forming the "Underground" system. This includes the District Railway with all its branches. On this line the particular system installed is the electro-pneumatic, modified to be automatic except at junctions. Signal cabins are placed only at junctions and at places where points require to be operated. The contrivance by means of which the train acts as its own signalman is briefly as follows. One rail of the running track is bonded, and is connected to the positive pole of a battery or generator. The opposite rail is divided into sections, each about 300 yds. long, bonded, but insulated at each end from the rails of the adjacent sections and each section is connected to a common negative main through a resistance. A relay is placed at the beginning and at the end of each section, and is connected across from the positive to the negative rail. Current flows and energises the relay, in which condition the relay completes a circuit to the electromagnet operating the admission valve of the air cylinder on the signal post, the air is admitted, and the signal arm is held off. This is the normal condition at each end of the circuit. When a train enters a section it short-circuits the relays through the wheels and axles, in consequence of which the relays, de-energised, break the circuit to the admission valve, which closes and allows the air in the cylinder to escape, and the signal arm, moved by gravity alone, assumes the "on" or danger position. At the same time the short-circuit is removed from the section behind, directly the train leaves it, the relays are at once energised, the admission valve to the air-cylinder on the protecting post of the section is opened, air enters and the signal is pulled down to the "off" position.

The speed at which traffic can be operated by this system of power signalling is remarkable. At Earl's Court junction box 40 trains an hour can be passed each way—that is 80 per hour—handled by the one signalman in the box. As the train approaches the box both its approach to the section and its destination must be notified to the signalman. When it is remembered that with ordinary signalling, to take an express train for example, a signalman hears some 24 beats on the gongs in his box, and sends signals to the front and rear box which give altogether some 24 beats on the gongs in these two boxes, 48 definite signals in all, for every express train he passes into the section which his signals protect, it will be understood that the

Digitized by Google

system must be profoundly modified to admit such a speed of operation as 80 trains per hour per man. The modification is radical. No gong signals are used at all. There is a small cast-iron box standing opposite the signalman with 15 small windows in it, each about 1½ in. square. Normally each window frames a white background. A click in the box announces the approach of a train, and a tablet appears in one of the empty windows showing by code the destination of the train. The signalman presses a plug in the box, a click is heard, and a tablet is seen in a precisely similar apparatus in the next box. When the train passes the man presses another plug and the tablet disappears.

Four wires run between the signal boxes along the railway, and by combining the currents along the four wires in various ways 15 definite signals can be obtained, a number sufficient for the District traffic. Each of the 15 combinations is arranged to operate one particular tablet in the box. Current from these four wires is tapped off at intermediate stations, and is used to work a train indicator showing the passengers assembled on the platform the destinations of the next three trains. The whole equipment is a triumph of ingenuity and engineering skill, and it is a splendid example of the way electricity may be used to improve the railway service quite apart from its main use in connection with the actual driving of the trains.

The facts and problems I have brought before you will, I think, show the important influence that scientific discovery has had upon our railway systems. When engineers endeavour to apply the results of scientific discovery they often find themselves confronted by new problems unperceived by the scientist. Together they may find a solution and thus enlarge the boundaries of knowledge and at the same time confer a practical advantage on the community. The pure scientist, the practical engineer, act and react on one another both to the advantage of pure science and to the advantage of the national welfare. The future success of our railways depends upon the closer application of scientific principle both to the economic and engineering problems involved in their working, some decrease in unprofitable competition with one another, and a more just appreciation by the State of the part railway companies play in our national well-being.

RECENT PATENTS IN WIRELESS TELEGRAPHY.*

BY W. H. ECCLES, D.SC.

We will take first the developments in methods of generating oscillations. Of these the method in which a fairly high voltage discharge takes place between metal surfaces in rapid relative motion is prominent. It may be recalled that in one of the original forms of Marconi discharger for producing a musical note, the discharge took place across a gap when it was almost bridged by copper studs carried on a rotating disc. Now types of discharger are described in which the discharge gap is formed by electrodes that move in opposite directions. Specification 17,505 (1908) shows two discs running in separate insulated bearings with their shafts in line and with their opposed flat faces rather close together. Each disc carries two symmetrically placed pegs ; and the discharge takes place across the narrow gaps between the pegs when they pass one another. It is stated that the best material for the pegs is copper—a fact fully accounted for by the high thermometric (as distinct from calorimetric) conductivity of the metal. It is also stated that in order to get the best results in producing oscillations, the time-period of the generator circuit with its choking coils must be an integral multiple of the interval between successive discharges of the primary condenser. Specification 8,581 (1909) is different from the last only in having the discs rotating in the same direction, which, no doubt, makes a better mechanical job, but there is the disadvantage that the discs must now be geared together. On the shafts of the two discs (Fig. 1) are two equal pinions gearing with an intermediate pinion in such a way that pairs of studs pass when on the line joining the centres of the discs. The discs may be rotated by a single motor driving the pinion, but it is better to use two similar motors, one driving each disc, so that the gearing transmits only half the difference of the powers of the motors at any moment. These simple improvements over the original forms of disc discharger give two benefits, first, the number of discharges per second is doubled; second, the duration of the discharge is reduced. The first means that the musical note can be more easily maintained ; the second brings more important advantages, especially if long waves are being produced. When the spark starts across the gap between two studs approaching one another, the condenser begins an oscillatory discharge. If the period of oscillation is long, comparatively speaking, the teeth separate and the spark dies down before many oscillations take place. Meanwhile the aerial coupled to the discharge circuit has been

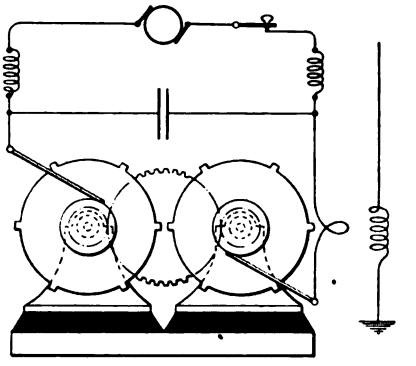

FIG. 1.—G. MARCONI, No. 8,581 (1909).

quickly urged into vibration ; and if, as is the case in the transatlantic stations, for example, the damping of the aerial by radiation (and it is to be hoped, by Joulean waste also) is small, the aerial will go on vibrating long after the the spark is finished. A rough guess at the peripheral speeds and the voltages leads one to suggest that about 25 oscillations occur before the primary is opened by the extinction of the spark—but this is a long shot. Thus this disc discharger, when used with long waves, gives the advantages of singleness of wave, very slight damping, and operation off a direct-current supply.

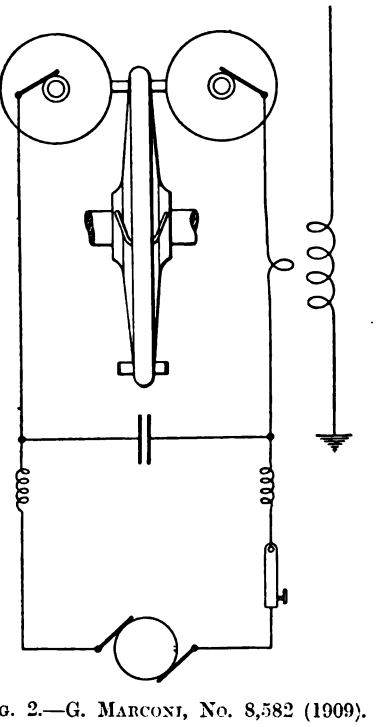

FIG. 2.—G. MARCONI, No. 8,582 (1909).

Another patent possessed by G. Marconi and Marconi's Wireless Telegraph Co. is No. 8,582 (1909) (Fig. 2). The generator is connected through inductances or resistances to a condenser, which is part of the oscillation circuit, and which is in series with the primary of the oscillation transformer. The terminals of this circuit are discs, which may be rotated to prevent burning, and the circuit is closed at regular frequent intervals by a rapidly rotating wheel that carries on its

Digitized by Google

periphery yielding metal bridging pieces, such as studs with spring tops or studs supported on springs. It will be seen that in this mode of generating oscillations the inventor passes from the principles underlying his other generators just described, to the opposite extreme; instead of cutting short the primary vibration at the earliest possible moment, the primary vibration is encouraged by the provision of a low resistance path to persist as long as possible. The prime requirement for the success of such a method is that the process of short-circuiting the gap should take place in a time that is small compared with the period of the oscillation generated. This is not easily done, for the oscillations may start, and even finish, long before complete closure can be effected, unless the mechanical motions are exceedingly rapid or the electrical oscillations are exceedingly slow, as these things go. The specification points out that low voltages can be used; probably only very low voltages can be used, and therefore, in order to get power enough, large currents must be made and broken by the moving bridging pieces. I recall that in some old experiments of my own on generating quite feeble oscillations by a similar process, in which a toothed wheel made and broke a current under 4 volts pressure, the energy losses at the minute spark gap were enormous unless the wave length was several thousands of metres. It must be added that in this method of generating oscillations the primary circuit is kept coupled to the aerial, and therefore, in general, two waves are radiated.

Two important methods of generating oscillations are described in Nos. 17,349 (1908) and 6,424 (1909). The earlier one is that of Egbert von Lepel, the latter is the method used

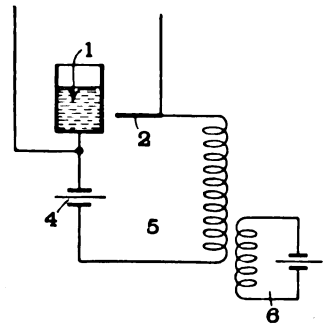

Fig. 3.—S. Eisenstein, No. 5,578 (1909).

by the Gesellschaft für Drahtlose Telegraphie. Both methods are stated to utilise that form of shock excitation first properly explained by Wien, and the plant for both methods has been fully described and discussed in former numbers of The Electrician. In both, the discharge of the primary condenser is made to take place between very close large metal surfaces, which are cooled to prevent the primary oscillation persisting long enough to affect the period or the damping of the secondary oscillation after this has once started. The Telefunken specification lays stress on the use of alternating current of rather high frequency with a number of gaps in series, and proceeds to elaborate the constructional details worked out for cooling the metal plates and providing for the easy and accurate assembling of these plates. It is stated that with a single pair of plates the range of transmission is only 50 km. to 100 km., and that therefore a number of gaps is essential. But surely this figure depends on the electrical dimensions of the primary circuit. The reason assigned for using alternating instead of direct current is that with the latter a definite place is soon selected for jumping the gap, with the result that the surface is soon spoiled and the whole arrangement put out of action. It may be mentioned that the use of an alternating current of musical frequency is not, as such, protected in this patent.

Another method that must be included in the shock excitation class is laid down by S. Eisenstein in 5,578 (1909) and 17,217 (1909). The spark is made to occur at a gap possessing strong rectifying properties. In Fig. 3 the gap is shown between the electrodes 1, 2. When the spark occurs the condenser 4 discharges suddenly, and, since the gap permits of current in only one direction, without vibration. The sudden discharge starts circuit 6 into vibration, and as the gap in circuit 5 is now open the former circuit vibrates in its own period. The present invention is merely concerned with the details of the valve or rectifier. The valve action is produced by keeping one electrode hot and the other cold. When a heavy feeding current is being used this current itself keeps the electrode 2 sufficiently hot, but otherwise special means such as a spirit lamp or an auxiliary electric arc is required. The advantage claimed is, besides singleness of wave, a very low rate of damping. This will enable sharp tuning to be obtained; and the inventor thinks that the efficiency will be good, especially if high-tension continuous current be used. In the above the vibration of the gap-circuit is supposed to be checked at the close of the first half period of that vibration. In a further specification, 17,217 (1909), by the same inventor, a method is suggested in which the process is checked after one complete oscillation. This is managed, according to the inventor, as follows:—The pointed or hot electrode of the rectifying valve is connected with the negative pole, and the cooled electrode of large area with the positive pole. The tension of the feeding current is selected in such a manner that it is at the limit of the penetrating force of the valve, so that, in the first place, the current passes from the large to the pointed electrode. Then "a fresh current in the opposite direction takes place, but a further passage of current, and consequently a continuation of the oscillation process, is prevented because in the meantime the energy of the oscillation has diminished so that the passage of current in the direction of the first half period is impossible."

A quite different purpose is held in view by M. Monasch, whose primary object is to provide a means of producing

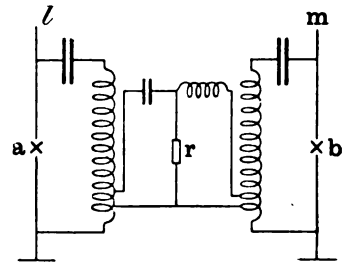

Fig. 4.—M. Monasch, No. 9,427 (1909).

phase-displaced oscillations, that is, of producing in two or more circuits vibrations possessing predetermined phase differences. The invention consists in bringing two or more sources of undamped, or but slightly damped, vibrations into connection with one another in such a manner as to establish a continuous mutual control that will maintain the desired phase-differences. Three ways of doing this are spoken of. Firstly, one or more of the sources of oscillations can be made predominant so that each of these compels one or more other sources to oscillate in definite phase relation to it. Secondly, every one of the sources may be made to participate in the control actively in such a manner that each of the mutually influencing sources vibrate in the desired phase. Thirdly, these two modes of operation may be combined with one another. In Fig. 4 is shown diagrammatically a means of persuading two sources, here supposed to be vibratory arcs, so to influence one another that their phase difference is anything desired. Here *a*, *b* represent Poulsen arcs, *l*, *m*, aerial conductors, and *r* an adjustable resistance. The intermediate circuit containing *r* establishes the connection between the sources *a*, *b*. It is not explained within what limits phase displacements are obtainable, nor is it stated which mode of vibration set up in any particular circumstances is the important one—though in a group of circuits coupled as here shown there are four possible free periods of vibration.

Finally, among methods of generating, that of E. Huth, 15,891 (1909), may be mentioned. In this an arc shunted in the usual manner is formed between two diverging electrodes simila- to the horns of a lightning arrester. The arc, it is

Digitized by Google

claimed, is thus intermittently elongated and broken by the rush of heated air; but the advantages of this are not very apparent.

Turning to methods of producing signals, and kindred matters, we find in R. A. Fessenden's specification, 14,826 (1909) a noteworthy mode of operation described. It is based on the principle that the frequency of a high-frequency current through any circuit in series with a high-frequency alternator undergoes transient alteration when inductance is introduced into or removed from the circuit. The effect of introducing or removing an inductance is shown in Fig. 5. The frequency change endures, of course, only when the phase displacement produced by an inductance is in the act of being created or destroyed. Success in the application of this principle must depend largely on the possibility of introducing and removing the inductance without undue arcing. However this may be, the present inventor proposes to cause the

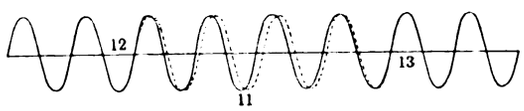

Fig. 5.—R. A. Fessenden, No. 14,826 (1909).

sending key of a telegraph station to alter in the above manner the frequency of the otherwise uniform stream of radiation from the aerial. The actual method of carrying out signalling is indicated in Fig. 6. Here 14 represents the armature of a high-frequency alternator possessing two windings, one extending from the point 15 to the point 16, and the other from the point 16 to the point 17. "The part extending from 16 to 17 is wound at a quarter phase difference from the part extending from 15 to 16 and the two parts are in series; 18 indicates resistances so adjusted as to maintain the intensity of the impulses constant when the coils 16 to 17 are inserted or cut out. 24 is a double-throw switch, 25 and 26 are commutators, either of which can be used as desired by throwing the double-throw switch 24. The commutators are preferably attached to the shaft of the armature 14. When the tele-

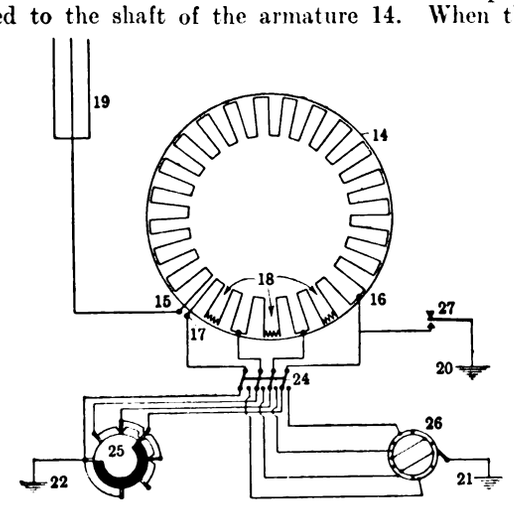

Fig. 6.—R. A. Fessenden, No. 14,826 (1909).

graph key 27 is up and switch 24 thrown to the left, commutator 25 is continually short-circuiting and opening the coils 16 to 17, and thus producing a fluctuating frequency which is higher than the normal frequency during one portion of the revolution and lower during the other. When the key 27 is depressed the section 16 to 17 is cut out, a steady frequency is generated and thus telegraphic signs transmitted." It is stated that this mode of sending does not disturb in any way the operation of neighbouring stations. This statement can be admitted if it be understood to mean that the neighbouring stations work with wave-lengths differing considerably from that of the station using the new device. No. 25,305 (1908) is another patent by R. A. Fessenden dealing with the broad question of telegraphic transmission. The objects of the invention are announced as the securing of secrecy, the attainment of high speeds of transmission, and duplex working. The essence of this very comprehensive invention is the proposal that instead of sending dots and dashes dots only are used, and the dashes and dots of the Morse code are discriminated by the employment of proper time intervals. Of course, the novelty of the invention does not lie in this proposition, but in the means designed for carrying it out. These means include devices for synchronising running machinery at the sending and receiving stations, which are worked out along obvious lines, but are much too complicated to describe here.

In specification No. 2,169 (1909), A. W. Sharman describes apparatus for transmitting signals by a method which is a development of that kind of wireless telegraph in which large currents are fed into two reasonably separated earth-plates at the sending station and small currents are picked up by two similar earth-plates at the receiving station. Instead of using

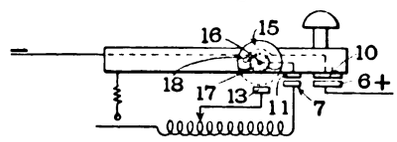

Fig. 7.—A. F. H. S. Simpson, No. 27,746 (1908).

continuous currents, the inventor proposes to use electrica impulses or shocks. The chief practical details described in the present invention may be summed up by saying that the shocks are produced by a sort of inductorium with only one winding—an auto-transformer, in short. By making tappings in this winding the primary and secondary portions may be given different proportions. Signals are made by making and breaking the primary current, and the consequent secondary impulses are delivered to the earth-plates. As for receiving, the principal thing required is a sensitive current detector. It is stated that the primary portion of the auto-transformer is best made larger than the secondary when working at sea, while the reverse is the case on land—a fact that may be explained by the lower resistance of the sea water circuit. In No. 27,746 (1908) A. F. H. Simpson developes an interesting proposal for combating wireless eavesdroppers. The inventor arranges his Morse key to change automatically the wave-length of the radiation, at more or less regular intervals, by its mere manipulation. A simple way of accomplishing this is to mount a ratchet wheel and pawl on the Morse key so that manipulation of the key lever causes the ratchet wheel to

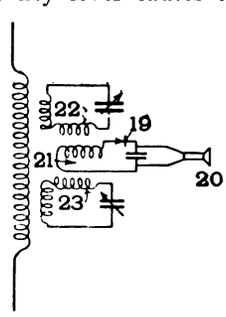

Fig. 8.—A. F. H. S. Simpson, No. 27,746 (1908).

rotate and connect up the different circuits in turn. Fig. 7 shows an arrangement for a two-wave station. 15 is a portion of a circular disc carrying the ratchet wheel 16 which is actuated by a pawl 18. As the wheel 16 rotates the contact 15–13 adds inductance to or subtracts it from the vibratory circuit. An eavesdropper with apparatus tuned sharply to one of the two wave-lengths of the sender would miss the dots and dashes sent on the other wave-length. The proper receiving station must be fitted in such a way that it receives both waves indifferently. Fig. 8 is a suggestion for the receiving circuits. Here the resonant circuits 22 and 23 are tuned to the two waves, and 21 is the detector circuit. A weak point of this particular design is that the aerial is out of tune with one or both of the resonant circuits, but this difficulty could be easily overcome.

(To be concluded.)

THE DIELECTRIC PROPERTIES OF MODERN HIGH-TENSION CABLES.*

BY M. HÖCHSTÄDTER.

Summary.—The author describes experiments made on paper cables at high pressures with a view to determining the dielectric losses in the insulation. The pressures were gradually increased until the insulation broke down; and from the oscillographic records, the author describes a method which he has devised for drawing the so-called hysteresis curve, corresponding to that for the magnetisation of iron. He also shows that there is apparently no "viscosity" traceable in paper cables, and that the breakdown takes place suddenly. He concludes with some remarks on the design of insulated transmission cables, and the effect of the choice of the value for the frequency.

Lately, and more especially in the last two years, great advances have been made in the manufacture of high-tension cables, particularly in the direction of higher breakdown voltage, greater uniformity in construction and increased mechanical strength. At the Siemens-Schuckert works the breakdown voltage over a short length of cable is at least ten times the working voltage. Polyphase cables for 10,000 volts are made to withstand 130,000 volts between the conductors, and for lower pressures the factor of safety is still higher. This paper is not concerned with details of manufacture, but is an enquiry into the problem, posed by the makers, as to the economies in thickness of insulating material which might be possible with higher voltages, seeing that the thickness of insulation is already reaching an impracticable limit. The

work of investigation, which occupied the second half of the year 1909 and some of the first months of 1910, deals exclusively with paper cables up to pressures of 60,000 volts.

The insulation resistance and its variations have often been examined. The losses in the dielectric, on the other hand, have received insufficient attention. Most of the work has been of the nature of a few physical experiments, carried out at low voltages. Very short lengths of cable have generally been used, and this tends to make the losses at the ends an undue proportion of the whole, which are only partly to be avoided by very awkward manipulative methods even for low voltages. A cable several hundred yards long is the least that is practically possible for our present purposes. Apt and Mauritius in 1904, and Humann in 1906, did some work on the subject of dielectric losses. The latter showed clearly the difficulties which attend measurements with a power factor of 0·03 and less. Humann, however, showed that the losses of a cable carrying no load were (within the limits he examined) proportional to the square of the effective volts and to the frequency. This shows clearly that the loss is not due to leakage, but to something dependent on the frequency, which is of the nature of dielectric hysteresis. For our present purpose it will be necessary to find the connection between the dielectric losses and the voltage for different dimensions of cables, having regard also to the effect of frequency and temperature.

The determination of the capacity is not always easy. Its value, as determined ballistically, is often very different from that given by alternate-current measurements. Something, doubtless, depends on the shape of the current wave and voltage wave; but it is not at all certain this explains everything. The breakdown voltage is a matter of the first importance, and in order to investigate it properly a method similar to that employed in testing the mechanical strength of a substance must be devised. Is there anything in a cable corresponding to the elastic limit, and do the properties of the dielectric undergo a change after passing a certain point before a breakdown occurs? This can only be determined by testing the value of capacity and hysteresis throughout the whole range. This would throw light on the disputed point as to whether a cable is injured by the nature and duration of the factory tests, and whether, for some reason or another, long lengths of cable are more liable to breakdown than short test pieces.

Fig. 1 shows the connections adopted generally when it was possible to earth one pole. [A slightly different arrangement was used when this was not possible, for which the original paper should be consulted, as also for a description of the instruments employed.] The ends of the cable had to be very carefully prepared, and this was so far successful that in a perfectly dark room at 50,000 and 60,000 volts it was only possible to notice the very faintest glimmer. Even with a long-continued pressure of 50,000 volts between the conductors of a polyphase cable and the lead covering the ends did not become hot. A protecting wire was used to prevent the end discharges from affecting the indications of the wattmeter; it carries the discharges directly to the corresponding pole, and these thus are shunted past the wattmeter. The most serious difficulties arose from the effect of the low power factor on the accuracy of the readings of the wattmeter, and this necessitated a great deal of preliminary work, which is fully described in the original paper, but for which it is impossible to find space here.

In order to study the laws relating to dielectric losses, it is proposed in the first instance to confine our attention to a certain cable which was very thoroughly tested. This was a three-core cable, each conductor having a section of 25 sq. mm., and being suitable for a working pressure of 5,000 volts. Its total length was 880 metres, and the thickness of the insulation

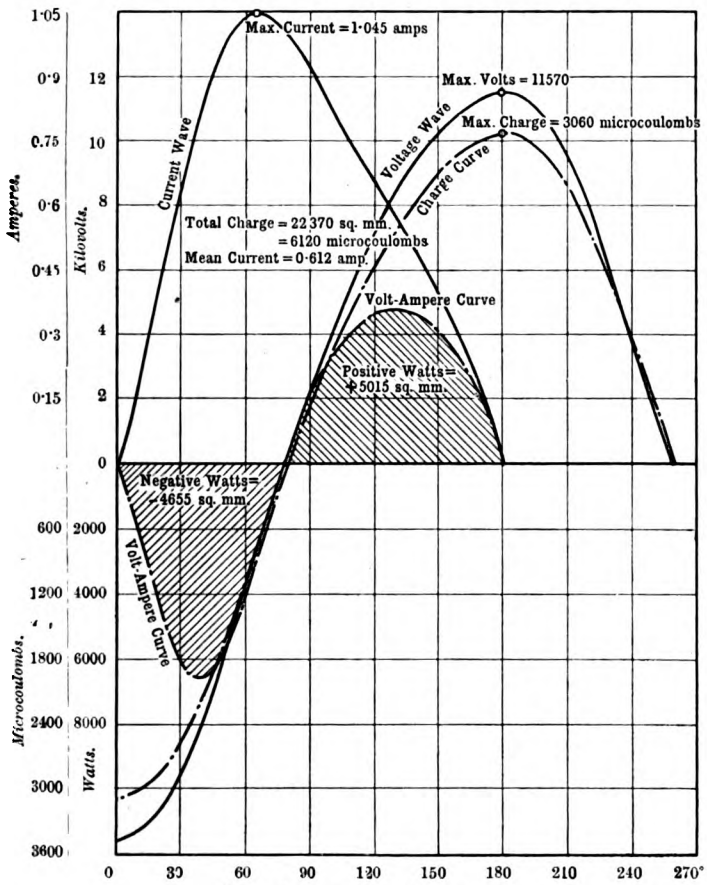
was 3·5 mm. Curves were first constructed showing the connection between the dielectric losses and the maximum of the voltage curve, taking account also of the effect of the frequency, which was varied from 30 to 60. These show that, although the amplitude factor varied from 1·33 to 1·41, the shape of the voltage curve does not affect the result, provided that account is only taken of its maximum value. The dielectric loss is exactly proportional to the frequency, and the readings were continued up to 20,000 volts on a length of 670 metres of cable. The figures obtained under test are given in Table I., which shows the values of the dielectric losses and of the capacity, as deduced from the oscillograms. A series of curves follows, by means of which it is shown how to draw the dielectric hysteresis loop from the oscillograms, which are first very carefully magnified by hand on accurately squared paper. Figs. 2 and 3 are typical of these curves. The resulting dielectric hysteresis curve is clearly analogous to that found



Dielectric loss = 5015 − 4655 sq. mm.
= 360 sq. mm.

i.e., dielectric loss per Km. = 199 watts: capacity calculated from maximum values of charge and volts per Kilometre $= \frac{3060}{11570 \times 0{\cdot}67}$
= 0·394 microfarad
Frequency = 50. Length of cable = 670 m.

FIG. 2.—CALCULATION OF OSCILLOGRAM.

in testing the magnetic properties of iron, with the understanding that amperes and volts are interchanged and magnetic induction is replaced by the electric charge on the cable. We see from the oscillogram that the maximum value of the voltage occurs simultaneously with the zero value of the current, and this occurred in all the paper cables under test, even at the highest voltages, at all frequencies and temperatures. In not one single oscillogram out of 100 was there the slightest trace of any deviation from this, not even in the case of very sharply pointed voltage curves. On the other hand, the maximum value of the current does not occur simultaneously with the zero value of the voltage. The values corresponding to the products of the instantaneous values of current and voltage are then plotted, the dielectric loss being obviously determined as being the algebraic sum of the positive and negative areas enclosed by the curve and the axis of co-ordinates. From these the dielectric loss could be finally estimated with the planimeter with an error of not more than 10 per cent., if extreme care were taken; but it was usually possible to get a more exact value from the hysteresis loop. In order to determine this loop, it is necessary to know the exact amount of the charge on the cable from instant to instant; but the oscillogram for the current values only allows a determination of the total charge by measuring the area enclosed between the current curve and the axis. By doing this in sections it is possible to determine the charge which flows in during the successive intervals, and in this way a curve connecting the voltage with the charge can be constructed. Seeing that the maximum of the voltage curve always coincides in point of time with the zero of current, and also with the moment of maximum charge, it is evident that there is nothing of the nature of "viscosity," and the hysteresis curve ends in sharp points. The similarity of this curve to that for the magnetic hysteresis of iron is very marked, except for the fact that in this case the lines forming the curve are more or less straight. The lower line is, indeed, almost exactly straight, whereas the upper, showing the descending charge, is very slightly curved. The characteristic of the sharp tip is present in both curves. It is possible to speak of a "coercive force" and a "residual charge" exactly in the same way as in the case of the magnetism of iron, for a charge still remains on the cable when the voltage has reached its zero value. The capacity of the cable corresponds precisely to the permeability of the iron, and is the

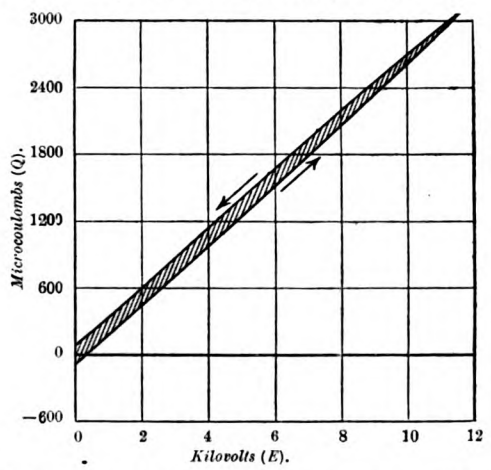


FIG. 3.—DIELECTRIC HYSTERESIS CURVE FOR A MAXIMUM APPLIED VOLTAGE OF 11,570, DRAWN FROM THE CURVES FOR CHARGE AND VOLTS SHOWN IN FIG. 2.

ratio of the charge to the voltage. Taking instantaneous values in the neighbourhood of the axis of x, it passes through the values of zero and infinity in rapid succession. The "true capacity" is best taken as being the ratio of charge to voltage when both have their maximum values. From these facts we may conclude that the dielectric loss in a cable is of the nature of hysteresis, and is a kind of internal friction which opposes electrification.

It has already been pointed out that the "true" capacity of a cable, as estimated by alternate-current measurements, is best calculated from the curve showing the hysteresis loop, and can be taken as being the ratio of the charge to the voltage when both have their maximum value. From a large number of oscillograms the "true" capacity of the given cable was found in this way, and in all cases the value was found to be the same. This leads us to think that the method gives the true value, seeing that the maxima of the two quantities are coincident in point of time, and, in the absence of any sign of "viscosity," are obviously physically correlated. This value of the capacity is neither affected by the shape of the wave form nor by the voltage nor by the frequency. Another method of estimating the capacity is by means of the formula connecting it with the effective values of voltage and current, and depending obviously on the shapes of the waves. But this gave values which differed in extreme cases by as much as 50 per cent. It can also be determined ballistically by direct current in the

Digitized by Google

usual way, and this leads to the interesting fact that the value found in this way agrees almost exactly with the so-called "true" capacity, the greatest difference that was noted amounting to about 3 per cent., which is within the limits of errors of observation. The numerical results of several tests are given, showing that the "true" capacity of the cable at normal temperature and at voltages up to six times that of the working voltage is constant, and the same as that determined by statical methods.

The next point for investigation was the effect of temperature, and for this purpose the cable was gradually heated by the passage of a suitable current up to 60°C. The testing pressure was 14,000 effective volts, with a maximum of 19,500 volts. The results are shown in Fig. 4. At 60°C. the asphalt covering was becoming soft, and the same applied to the impregnating substance of the cable. It was found that the dielectric loss fell steadily up to 40 deg., at which point there seemed to be a minimum. At 60 deg. it seemed to be rising again. Humann seems to have found very similar results. The insulation resistance decreased in the well-known fashion according to an exponential curve, as shown by the straight-line curve, giving the logarithm of the megohms. It will be noticed that the ballistic method seems to show a great increase in the value of the capacity with a rise of temperature; but this is an illusion, and depends on the fact that the insulation resistance falls, and this, of course, affects the galvanometer

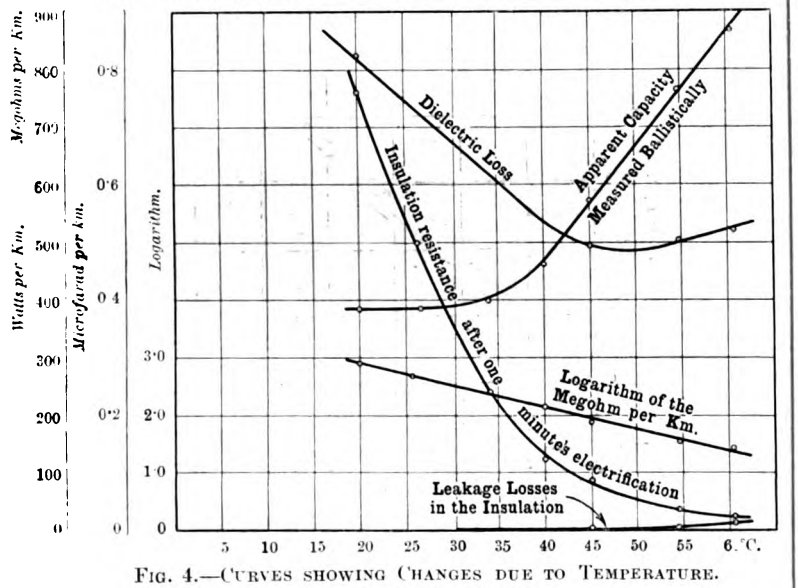

FIG. 4.—CURVES SHOWING CHANGES DUE TO TEMPERATURE.
Length of Cable = 670 metres.

reading. Measured by alternate-current methods, as described earlier in this paper, the capacity was found to be absolutely constant during the test extending over six hours, during which the temperature was gradually raised to 60°C. This shows that no internal change takes place within the cable even under these trying conditions, which are, of course, below the region of the breakdown voltage; and after the cable had cooled and resumed its normal condition it was found that it had sustained no damage whatever, and that the insulation resistance had its normal value.

The point in the neighbourhood of the breakdown voltage was next examined, and measurements were made at voltages between 15,000 and 50,000. In the first instance, curves were constructed up to a point near that of breakdown, and subsequently the cable was submitted to long-continued pressures a good deal below this point. A length of 200 metres of the cable was taken, and the pressure was between the three conductors and the lead covering, as shown in Fig. 1. At 45,000 volts there were slight but unmistakable signs of a probable breakdown, and, though a momentary pressure of 49,600 volts (effective) was applied, no oscillographic records were taken at this point. The readings, however, were perfectly steady up to this point, and showed that the true capacity remained perfectly constant, and the dielectric losses increased according to a steady curve, which showed no trace of any unusua change, even in the neighbourhood of the breakdown point. The cable was then tested for three hours at 25,000 effective volts, and then on the next day for three hours at 34,100 effective volts. Beyond such small changes as were traceable to a slight increase of temperature, no changes whatever were found to have taken place in any of the properties of the cable. Finally, the cable broke down after being submitted to an effective pressure of 45,500 volts for three minutes, and the readings, taken an instant before the cable broke down, showed that it had up to that stage experienced no change whatever. A large number of test pieces of the same cable were then taken, and the voltage was gradually raised in each case till the breakdown took place. These tests tended to show that there was no noticeable difference between the longer and shorter lengths, and that for all practical purposes it might be said that the breakdown voltage did not depend on the length of the cable, and that in all cases the breakdown took place suddenly and without any marked premonitory symptoms. The insulation was of such a character that a pressure of about 20,000 effective volts was required to break down an average thickness of 1 mm. of the insulation.

Curves are then given showing the dielectric losses in cables of different types and lengths, the thickness of the insulation, and also its weight per metre run, being stated. These curves naturally vary considerably; one general conclusion, however, seems to be that the dielectric loss in three-core cables at high voltages depends rather on the intensity of the applied voltage than on the type of cable. For instance, at pressures above 30,000 maximum volts, there was found to be very little difference between a cable which had a thickness of 3·5 mm. of insulation and others which had 12 mm. or 13 mm. of thickness, the weights per foot-run in the latter cases being 9 or 10 times that in the former. With single-core cables the same is true to some extent, but the losses are naturally less than in a three-core cable with the same thickness of insulation. The so-called "specific dielectric loss" is calculated in watts per kilogramme of insulating material per metre-run, the abscissæ of the curve being volts per millimetre thickness of the insulation. In the case of the cables with thicker insulations, it was found that the "specific" losses increase very quickly with a rise of voltage. A careful individual examination of various types of cables is next made, and results, including curves for some of these, are given, the pressures applied in some cases rising to nearly 100,000 maximum volts.

The author concludes with the comparison, for three-phase transmission, of one three-core cable with three single-core cables, the total weights of insulation applied to the cable or cables being in the two cases approximately the same. Up to 30,000 effective volts there seemed very little difference between the two; at 50,000 volts and a frequency of 50, the dielectric loss per kilometre was 4·5 kw. for the three-core cable, as compared with 2 kw. for the three separate cables. At 60,000 effective volts, the corresponding figures were 7·5 kw. and 3 kw. respectively. The question is—how far these figures should affect the design of a transmission scheme. It may be assumed for our present purpose that insulated cables are considered advisable owing to some local necessity, and that overhead cables have been thought unsuitable. The capacity of a system of insulated cables is 15 or 20 times that of overhead cables; in the latter case, the figure may be taken at about 0·01 mfd. per kilometre. This, however, is only one reason out of many for choosing a low frequency. The examination of a particular case will help to explain matters. The three-core cable may be supposed to transmit a full load of 15,000 kw. over a distance of 50 km., the power factor being 0·85, the pressure 50,000 volts and the sectional area of each conductor being 100 sq. mm. Let us take two cases in which the frequency is (1) 50 and (2) 15. Each phase carries 203 amperes, and the losses in ohmic resistance are 21·7 kw. per kilometre. Therefore, over 50 km., 1,085 kw. are lost from this cause. The dielectric loss for a frequency of 50 is, according to our tests, 225 kw. for 50 km., and for a frequency of 15 it is 68 kw. The resulting total efficiency at full load is 92 per

Digitized by Google

cent. for a frequency of 50, and 92·7 per cent. for a frequency of 15. In this case there seems, therefore, no great difference between the two. But at no load things are different. With a capacity of 0·2 mfd. per kilometre (as found earlier in this article), the charging current is 95 amperes for a frequency of 50 and 28·5 amperes for a frequency of 15; and the ohmic losses due to currents of these magnitudes are, relatively speaking, serious. Taking the total yearly results, and supposing the average load to be 40 per cent. of the full load, the losses are as follows: For a frequency of 50 the ohmic losses are 3 per cent. and the dielectric losses 4 per cent. of the total output, the resulting overall efficiency being 93 per cent.; with a frequency of 15 the ohmic losses are, as before, 3 per cent., and the dielectric losses 1 per cent. of the total output, the efficiency being therefore 96 per cent. When translated into pounds, shillings and pence the advantage resulting from the lower frequency appears very great. [The above case is fully worked out in the original paper, though it is treated very briefly here; account is taken of the reaction of the charging current on the ohmic losses, having regard to the difference of phase between it and the working current.]

We thus see that at 50,000 volts the dielectric losses are of the same order of magnitude as the ohmic losses, and that if a sufficiently low frequency is chosen it is quite reasonably possible to use insulated cables somewhat of the type described for transmission purposes. Insulated cables with conductors of small sectional areas, intended for carrying comparatively small loads, are unsuitable, partly on account of the charging current and partly owing to dielectric losses. In the case examined above the cable should not be more than about 100 km. long. In concluding the comparison of the three single cables with one three-core cable, the case may be thus stated: A given weight of insulation is more effectively applied to a three-core cable, but the dielectric losses are in this case nearly twice as great as in the other. The capacity of the single-cable system is 0·162 mfd. per kilometre, as compared with 0·2 mfd. per kilometre, and these figures have a corresponding effect on the overall efficiency. The cost of three single cables, including armouring and laying, is obviously greater than that of the three-core cable; but the single-cable system has an undoubted and probably deciding advantage in the ease with which joints can be made.

It remains to be said that during the time the present paper was in the press the author's attention was drawn to the work of H. F. Haworth, who investigated the dielectric properties of porcelain plates. It is not possible here to discuss his results, which seem to differ from those here set forth. In any case, it is very probable that the nature of dielectric losses cannot be stated in general terms, but that much depends on the particular substance under consideration. Some substances may show signs of viscosity and polarisation, while others do not do so. The author does not claim that his results apply generally, but only to the materials used by the Siemens-Schuckert works for the insulation of their cables. If other substances behave in a different way, this shows that the insulating medium selected for the Siemens-Schuckert cables has been the result of a very happy choice, since its properties are similar to those of an ideal dielectric.

NEW POST OFFICE TELEPHONE EXCHANGE AT GLASGOW.

(*Concluded from page 811.*)

In connection with the junction working, some interesting departures from present practice have been introduced. The incoming order wires terminate upon break jacks which are provided so that a faulty order wire may be quickly substituted by a good incoming junction. It is only necessary for the operator to insert the plug of the incoming junction selected for the purpose into the break jack associated with the faulty order wire. All incoming order wires are connected to the main springs of a position throwing key, the object of this key being to transfer groups of incoming wires to the next succeeding position during slack periods. In order to facilitate testing the common connection which normally joins all the position plug tips together, and to the 58-ohm winding, is also transferred by the action of the position throwing key. The operation of the junction supervisory relay when a B. operator responds to a ringing junction call is assisted by a 1,400-ohm retardation coil placed across the common leads of the speaking keys. A signal is also given to the distant A. operator, and the machine ringing key is released at an intermediate point if the operator, when using the junction to connect a third exchange, had inadvertently depressed this key.

As regards the incoming junction from common battery exchanges, it has been customary to provide for four party lines with selective ringing by placing the five ringing keys in the speaking circuit. In the present case, however, the ringing keys are quite independent of the speaking circuit. The connections for the busy-back jack are similar to those employed in the Department's existing busy-back circuit. The machine ringing arrangements are of a special character, and an illustration of a machine ringing and speaking key is given in Fig. 14. A locking plate is provided, which is common to all the five buttons, and a relay circuit is closed when any button is pressed down as far as it will go. When the button is released it travels upwards to a half-way position in which it engages the clutch of the locking plate. The button remains in this position even when the ringing circuit is automatically disconnected from the junction circuit, until some time later another button is depressed, when the locking plate is forced outwards from the shoulder of the plunger. The half-way position is an advantage because the B. operator, if asked to ring a subscriber a second time, can distinguish the button previously depressed. Each ringing button for the party line service has control of six key springs, which when the button is depressed select the type of ringing current required for the subscriber's circuit. Osram

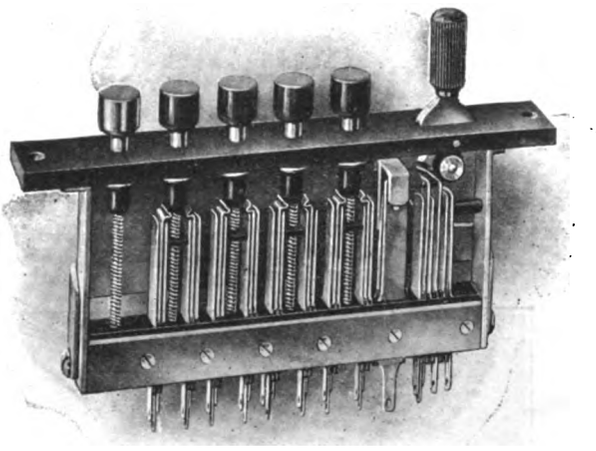

FIG. 14.—SPEAKING AND RINGING KEYS.

resistance lamps are inserted for protective purposes between the positive and negative pulsation brushes of the generator and the machine ringing key. Party line ringing, as well as ringing for ordinary lines, is intercepted by interrupters which give one second ringing period and two seconds interval. These interrupters are inserted between the generators and the resistance lamps.

The "three-lamp set" commonly used for testing in C.B. exchanges was modified for the present exchange. 36-volt lamps are used for the tip, ring and sleeve circuits. The treatment of a typical fault may be referred to in some detail, namely, "tip" conductor of subscriber's line circuit to earth. In this case the earth will reduce the sensitiveness of the line and supervisory relays, also it will unbalance the transmission circuit. The tip lamp of the set will glow intensely when the peg of the tester is inserted into the jack of the faulty line. Depression of the S key of the tester in the majority of cases will not cause the tip lamp of the set to darken. In the minority of cases the fault will be between the cut-off relay springs of the line relay coil. Under these conditions the sensitiveness of the line relay is reduced but not that of the supervisory relay; the insertion of the peg causes the tip lamp to glow brightly as before, but the depression of the key causes the darkening of the tip lamp. The latter fault though unusual is very serious, and to locate it the resistance in series with the sleeve key of the tester is of such value that the depression of the key will not actuate either cut-off relay when two are in multiple, but one relay only by itself.

The switchroom desk equipment has been made very complete. The information desk is in two sections of two positions each, and extensions can be readily made. The information operators attend

ELECTRICAL RECORDING THERMOMETERS FOR CLINICAL WORK.*

BY H. L. CALLENDAR, LL.D., F.R.S.

Summary.—The conditions of sensitiveness in measuring a resistance by the Wheatstone bridge method are first discussed; after which the author proceeds to describe the construction of electrical resistance thermometers and recorders for clinical work.

The scientific interest and importance of a method of continuously recording the temperature of the body, whether in health or disease, is now being generally recognised. My attention was first directed to the subject by Prof. J. G. Adami, F.R.S., of McGill College, Montreal, at whose suggestion I constructed some electrical resistance thermometers specially adapted for recording the temperature of different parts of the surface of the body. Unfortunately, I had to leave Montreal early in 1898, before the apparatus had taken its final shape. I returned to the subject in November, 1908, when I undertook to make some thermometers for Dr. A. Gamgee, F.R.S., and to collaborate with him in evolving a practical method suitable for general use in clinical work. He had become convinced that the thermoelectric method was unsuitable for general use, on account of the delicacy of the apparatus, and the necessity for employing an elaborate thermostat. A serious difficulty in practice was the necessity of keeping one of the junctions of the couple at a constant temperature in the neighbourhood of 37°C. for long periods. In the application of the resistance method no thermostat was required, and it was easy to obtain a tenfold larger deflection with the same galvanometer. The objections that have commonly been urged against electrical resistance thermometers for this kind of work are (1) that resistance thermometers are more difficult to construct and to insulate satisfactorily than thermocouples, and (2) that their indications are liable to be disturbed by the heating effect of the current employed. These objections undoubtedly exist, and have

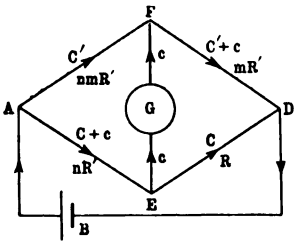

FIG. 1.—DIAGRAM OF WHEATSTONE BRIDGE.

frequently proved fatal to the employment of resistance thermometers, but they have arisen chiefly from faulty application or construction, and not from defects inherent in the method. Objection (1) is readily surmounted by proper methods of construction, and objection (2) by a proper consideration of the conditions of sensitiveness.

Conditions of Sensitiveness.—The conditions of sensitiveness in measuring a resistance by the Wheatstone bridge method have been discussed by Maxwell and Heaviside, whose results have generally been quoted and applied to the problem under consideration. They start with the assumption that the battery power available is limited by the internal resistance of the cells, and give rules for obtaining the maximum current through the galvanometer with this implied limitation. The limitation of battery power was no doubt an important consideration in many kinds of telegraph testing 30 years ago, but it is rarely applicable in modern laboratory practice, and never in dealing with electrical resistance thermometers. In the majority of resistance measurements and more particularly in electrical thermometry, the limiting condition is imposed by the heating effect of the current on the resistance to be measured, and the resistances, &c., should be chosen and arranged to give the greatest sensitiveness for a given limiting value of the current through the resistance to be measured. The resistance of the battery circuit is quite immaterial, provided that the battery can be arranged to give the required limiting current. The problem has been discussed from this point of view by Guye and by Schuster, and in several of my own Papers, but it will facilitate discussion to reproduce here the investigation itself in a simplified form.

Let Fig. 1 represent the arrangement of resistances in a Wheatstone bridge, in which C is the current through the resistance to be measured R, and c is the current through the galvanometer of resistance G, when the bridge is not balanced. The resistance in series with R is nR' traversed by a current $C+c$; the resistance in parallel with R on the same side of the galvanometer circuit is mR' traversed by a current $C'+c$. The resistance in the opposite arm of the bridge to R is nmR', traversed by a current C'. The currents are assumed to flow in the directions indicated by the arrows, and it is evident that they satisfy the condition of continuity. The numbers n and m, representing the ratios of the arms of the bridge, may have any positive values. The bridge is balanced when $R=R'$, in which case $c=0$, and $C'=C/m$. Since the difference of potential between the ends of the galvanometer circuit is Gc, we have by Ohm's law,

$$RC-mR'(C'+c)=Gc=nmR'C'-nR'(C+c).$$

Eliminating C', we obtain for the ratio c/C,

$$c/C=(R-R')/(G(1+n)/n+(1+m)R'). \quad . \quad . \quad . \quad . \quad . \quad (1)$$

It is obvious that this ratio, which may be regarded as a measure of the sensitiveness of the arrangement, is quite independent of the resistance or E.M.F. in the battery circuit. It is also at once evident that, for a given defect of balance, as measured by $R-R'$, the value of the ratio c/C will be a maximum when n is as large as possible, and m as small as possible, the limiting value of the ratio c/C in this case being, when

$$n=\infty, \text{ and } m=0, \; c/C=(R-R')/(G+R').$$

This point has been emphasised by both Guye and Schuster, and comes out clearly in Heaviside's investigation. The advantage which can be gained by making n large and m small is not very great, because when $n=m=1$, $c/C=(R-R')/2(G+R')$, or the sensitiveness is still half as great as in the limiting case. For practical purposes it is more important to observe that if n is small or m large, the sensitiveness may be indefinitely reduced. This arrangement should always be avoided if possible, as shown by the following example.

Maxwell has given a rule which is very often quoted and applied ("Electricity and Magnetism," Vol. I., section 348): "Of the two resistances, that of the battery and that of the galvanometer, connect the greater resistance so as to join the two greatest to the two least of the four other resistances."

This rule is seldom applicable to accurate resistance measurements, and when applied in platinum thermometry has often led to disastrous results. A simple numerical example will make this clearer. Suppose that it is required to measure the resistance of a platinum thermometer, R = 10 ohms, with a Post Office box having ratio arms 10 and 1,000 ohms. Suppose that the galvanometer has a resistance G = 10 ohms, and that the battery is a 2 volt cell of negligible resistance. According to Maxwell's rule we should connect the galvanometer so as to join the two resistances of 1,000 ohms to the two resistances of 10 ohms, in which case we should have $n=1$, and $m=100$ in Fig. 1. Suppose that the balance is slightly disturbed by a change $dR=R-R'$. Substituting in equation (1) we obtain:

Case (A), Maxwell's rule, $n=1$, $m=100$, $c/C=dR/1{,}030$, $C=0{\cdot}1$ amp.

If, however, we interchange the connections of the battery and galvanometer, which is simply equivalent to interchanging the values of n and m in the equation, we obtain for the anti-Maxwell arrangement:

Case (B), anti-Maxwell, $n=100$, $m=1$, $c/C=dR/30$, $C=0{\cdot}002$ amp.

The actual value of the current through the galvanometer in case (A) is greater than in case (B) in the proportion of 3 to 2. Maxwell's rule is so far justified. But the current through the resistance to be measured is 50 times greater in (A) than in (B), and the heating effect of the current is 2,500 times greater. With an ordinary platinum thermometer arrangement (A) might give an elevation of temperature of about 5°C., which would be fatal for any purpose of measurement. Whereas arrangement (B), with nearly the same sensitiveness, would give an elevation of 0·002°C. only, which is sufficiently small for the most accurate work. The essential point is to observe that the ratio c/C of the galvanometer current to that through the thermometer, which is the true measure of sensitiveness in this case, is 34 times greater in (B) than in (A). (B) is therefore by far the better arrangement in the case where the heating effect of the current on the resistance to be measured is the primary consideration.

The rule to replace Maxwell's in this case, if there is any choice as to the arrangement of the battery and galvanometer connections, is: "Connect the battery so as to make the resistance in series with the thermometer greater than the resistance in parallel." This will make n greater than m in Fig. 1, and it is evident that the ratio c/C will be diminished or the sensitiveness reduced, if n and m are interchanged.

In the practical use of platinum thermometers, we have the further restriction that n must be equal to unity, because it is necessary to compensate the changes of resistance of the leads by

* Abstract of Prof. Callendar's Presidential Address to the Physical Society.

Digitized by Google

the equal changes of resistance of a pair of compensating leads on the opposite side of the galvanometer contact on the bridge-wire. The loss of sensitiveness, as compared with the case of n very large, does not amount to more than 20 or 30 per cent., and is of no consequence as compared with the trouble and uncertainty involved in measuring the resistance of the leads separately at each observation. Moreover, if n is made large, the heating effect of the current C on the resistance nR' may become serious. As a matter of fact this is a common and very insidious source of error in the use of a P.O. box with $n=100$, especially if the coils are of german silver or platinoid. With maganin resistances the effect is much less marked.

It is still possible to gain some advantage in point of sensitiveness by making m smaller than unity, provided that it is not made so small that the heating effect of the current C/m on the resistance mR' becomes appreciable. For the most accurate work I have generally employed thermometers having a resistance about 25·6 ohms at 0°C., with a fundamental interval of 10 ohms, and have made the ratio coils about 6·4 ohms, giving $m=1/4$, which gives an advantage of about 20 per cent. in point of sensitiveness as compared with $m=1$. A more important consideration in this case is that the same box can be used with thermometers of lower resistance, *e.g.*, $R_0=2·56$ ohms, F.I.=1 ohm, without serious loss of sensitiveness.

Resistance of Galvanometer.—It is generally possible to vary the resistance of a galvanometer through a wide range, by altering the connections of the coils or by substituting one coil for another, without altering the mass of the coils. In this case the sensitiveness will vary approximately as the square root of the resistance G. We see from equation (1) that the deflection of the galvanometer, which is proportional to $c\sqrt{G}$, will be a maximum when $G=n(1+m)\,R'I(1+n)$. This result agrees with that given by Maxwell, and shows that in the majority of cases which occur in practice, G should be of the same order of magnitude as R, being restricted to the limits 2R and R/2, if n is never less than 1, or m greater than 1. If we are restricted, as in platinum thermometry, to the case $n=1$, we should take $G=(1+m)R'/2$. The best resistance for the galvanometer is restricted to the same limits, 2R and R/2, provided that m does not exceed 3.

For example, in the case of the box already quoted, with ratio coils 6·4 ohms, when used with a thermometer $R_0=25·6$ ohms, the best resistance for the galvanometer was 16 ohms. When the same box was used with a thermometer 10 times smaller, $R_0=2·56$ ohms, the best resistance for the galvanometer would be 4·5 ohms. This could be secured approximately by putting the two coils of the 16 ohm galvanometer in parallel, but the advantage gained thereby would be only 10 per cent. If, on the other hand, the ratio coils had been made equal to 25·6 ohms each, according to the rule given by Maxwell and generally followed, there would have been a loss of sensitiveness of 20 per cent. with the 25·6 ohm thermometers, and 50 per cent. with the 2·56 ohm thermometers, which could not so well be neglected.

Resistance of the Thermometer.—For a platinum thermometer of resistance R_0 at 0°C., the change of resistance per 1°C. is approximately 0·004 R_0, which must be substituted in equation (1) for the value of dR or $R-R'$, in order to find the deflection of the galvanometer per degree change of temperature. Making this substitution, and remembering that $n=1$, we find that, when the resistance of the thermometer is changed, the deflection per degree, which is proportional to $c\sqrt{G}$, varies as $RC\sqrt{C}/(2G+(1+m)R)$.

The rise of temperature produced in the thermometer by the measuring current C is directly proportional to C^2R and inversely proportional to the rate of dissipation of heat per degree rise of temperature of the thermometer above its surroundings. The rate of dissipation of heat depends on the form and surface of the thermometer, and on the conditions of exposure. For similar thermometers of different resistances, but of the same size, under similar conditions of exposure, we must have C^2R the same in order to secure the same degree of accuracy as limited by the heating effect of the current. The permissible current C will therefore vary inversely as the square root of the resistance of the thermometer. Making this substitution, we have

$$c\sqrt{G} \text{ varies as } \sqrt{G}R/(2G+(1+m)R).$$

We see from this result that, if it is possible to choose the best resistance for the galvanometer, namely $(1+m)R/2$, and if m is the same for all, the sensitiveness and accuracy of the thermometer, so far as the heating effect of the current is concerned, will be independent of its resistance. In accurate laboratory work, where a delicate galvanometer is available, the heating effect of the current is so small as to be relatively unimportant, and the resistance of the thermometer is chosen chiefly with a view to minimise errors due to defects of insulation or imperfect contacts, or small differences in the resistance of the thermometer and compensator leads. On the other hand, for practical applications, or for ink recording, it is necessary to employ a fairly robust and portable galvanometer of the suspended or pivoted coil type; the current employed must be considerably increased if a large scale record is required, and it may be important to choose the resistance of the thermometer to suit the galvanometer or vice versa, in order to minimise the heating effect of the current.

The symmetry of the above expression in respect of G and R shows that the condition governing the choice of the resistance of the thermometer, if the galvanometer is given and m is constant, is the same as that already given for the galvanometer in terms of R, namely, $R=2G/(1+m)$.

If, however, the value of $mR=S$ is constant, being fixed by the resistance of the ratio coils, each equal to S, of the bridge employed, the maximum sensitiveness is obtained when $R=2G+S$. The latter condition gives the limit beyond which no advantage can be gained by increasing R and diminishing m, even if the heating effect of the current on S can be entirely neglected. If the heating effect of the current in the thermometer is kept constant, as already assumed, the heating effect in S increases in proportion to R/S. On the same assumption the total current to be supplied by the battery (which is a consideration in records of long duration) is a minimum when R=S, but is only increased in the ratio 5/4 when R=4S. The maximum sensitiveness is obtained when S=0 and R=2G, but the sensitiveness will be reduced by little more than 10 per cent. if we make S=G/2, keeping R=2G. It would be reduced a further 20 per cent. if we made R=G=S, according to Maxwell's investigation.*

In employing the deflection method described below, the advantage of making R larger and S smaller than G is really greater than would appear at first sight, because, if the sensitiveness is reduced 20 per cent. for the same heating effect of the current, it means in practice that the current must be increased 20 per cent. to give the required deflection, or that the heating effect of the current must be increased more than 40 per cent. The most important error to avoid is to make R small compared with G or S. The sensitiveness may in this way be very greatly reduced, and the heating effect of the current increased five or 10 times. Thus, a pyrometer of low resistance designed for work at high temperatures (where the resistance is high and an open scale is not required) would not be a suitable instrument to employ for recording small variations of temperature on an open scale at low temperatures, unless G and S were made inconveniently small, and the pyrometer itself specially wound with extra thick wire to give a large cooling surface.

Construction of Thermometers.—The author proceeds to describe the construction of thermometers:—(1) For insertion in the mouth; (2) for the rectum; (3) for the surface of the skin or for the axilla (armpit).

A great improvement on the ordinary type of platinum thermometer in point of quickness of action and diminuation of the heating effect of the current, is readily effected by winding the wire on a *flat* plate of mica in place of a cross, and melting the lower part of the containing tube (which is preferably of lead glass) down on to the wire so as to form a flat bulb, as illustrated in Fig. 2. If the glass is thin, the sensitiveness may be increased nearly five times, as compared with a thermometer of the ordinary type, and the heating effect of the current reduced in nearly the same proportion. When inserted in a water bath at 37°C. this thermometer takes less than a minute in arriving within a hundredth of a degree of the final temperature; but when inserted cold in the mouth, it may take 4 or 5 minutes to get within a tenth of a degree, because the tissues of the mouth take time to recover from the cooling effect of inserting the thermometer. Where quickness of action is an essential condition, as in some kinds of calorimetric work, the flat-bulb thermometer is a great improvement on the ordinary type with a round tube, but it shares with the mercury thermometer the disadvantage that, if broken or damaged, it cannot easily be repaired.

It is essential that thermometers of this type should be provided with compensated leads, otherwise there will be a variable immersion error, and an apparent lag due to slow conduction of heat along the leads. It is also most important for accurate work to avoid screw terminals in the head of the thermometer, and to provide each instrument with flexible leads two or three metres long, permanently soldered to the thermometer and compensator leads, and securely attached to the head of the thermometer, as indicated in Fig. 2.

The smallest size of quartz-glass resistance thermometer constructed by Heræus has a bulb 25 mm. long and 3 mm. in diameter,

* Maxwell, "Electricity and Magnetism," Vol. I., section 349. This is the right arrangement if all the four arms of the bridge are similar, and equally affected by the current.

Digitized by Google

and is therefore very similar in dimensions to an ordinary clinical thermometer. The bulb contains a coil of fine platinum wire wound on a rod of quartz-glass, and protected by a very thin tube of quartz-glass fused over it. The bulb is fused on to a larger quartz tube, containing the two leading wires, which are of gold. The resistance of the coil is 25 ohms nearly at 0°C., but, as there are no compensating leads, the resistance cannot be measured very accurately. This type of thermometer is very suitable for insertion in the mouth but is unsuitable for records of long duration owing to its shape and the risk of breakage. It does not appear to be quite so sensitive as a mercury thermometer of similar dimensions, partly owing to the low conductivity of the central rod of quartz-glass, and partly to the fact that the leads are not compensated.

The author specially designed a flat platinum tube thermometer for calorimetric work, where quickness of action and small mass are important. It is similar to the flat glass bulb thermometer, except that the containing tube is of platinum about 0·05 mm. thick, which permits the thermal capacity of the bulb to be greatly reduced. The coil is wound on a flat plate of very thin mica, and insulated

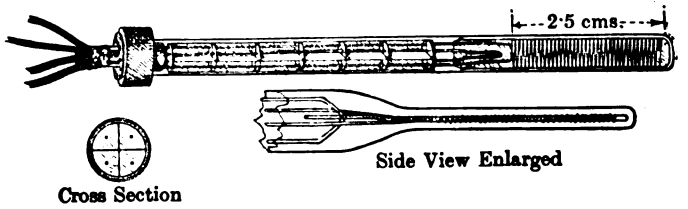

Fig. 2.—Flat Glass Bulb Thermometer.

from the flattened platinum tube by thin strips of mica on either side. Owing to its size and shape, it was not very suitable for insertion in the mouth.

A comparison of the records of the platinum tube thermometer (Pt) and the Heræus quartz tube thermometer (He) when placed in the mouth under similar conditions is shown in Fig. 3, which illustrates the importance of extreme quickness and small thermal capacity in such tests. It might appear at first sight as though the slow and long continued rise indicated by both thermometers in different degrees, was due to the heating effect of the measuring current, which might easily produce a result of this nature if the current were excessive or the mass considerable. But the current employed in taking these records scarcely exceeded one hundredth of an ampere, and the heating effect of the current was measured in both cases and found to be very small. Records proving that the apparent lag of the thermometer is really due to the slowness of recovery of the temperature of the mouth itself after being cooled in any manner are given by the author.

For records of long duration, the best results are undoubtedly to be obtained by insertion in the rectum. The thermometer bulb should be of small dimensions and the leading wires should be

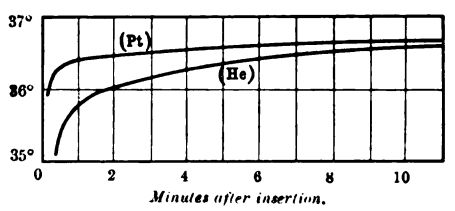

Fig. 3.—Comparison of Quartz and Platinum Tube Thermometers in mouth after closure for 10 minutes.

enclosed in a flexible but inextensible tube of small diameter, such that it can be attached to the bulb in a perfectly secure and water-tight manner. Such a thermometer may be made in a variety of ways. The following is a description of a method of construction which I have found very satisfactory. The fine wire forming the bulb is wound on a thin celluloid tubes, 5 mm. in diameter, and is protected by another thin celluloid tube which closely fits the first. One end of the protecting tube is closed by a small celluloid stopper, the other is cemented with celluloid cement to the cut end of a Porges catheter 5 mm. in external diameter, and 32 cm. long, through which the flexible thermometer and compensator leads are passed. Records obtained with this thermometer are given by the author.

A tube form of thermometer is not very suitable for surface use, since the contact between the thermometer and the skin is necessarily imperfect. It is desirable to give the thermometer as large a surface as possible, in order to diminish the heating effect of the current and to make the bulb flexible and thin. The first thermometer of this type which I constructed for Prof. Adami in 1897 was made by sticking a thin bolometer grid of platinum foil on to a thin sheet of celluloid photographic film. The substitution of fine wire for the foil greatly facilitated the construction and adjustment, and was found to make little, if any, difference to the sensitiveness. In any case it is most important that the thermometer should be fairly robust, as it has to undergo somewhat rough usage. In my experience nothing answers so well as celluloid film for the insulating material, the thermometer can preferably be inserted in a thin flat celluloid sheath. A surface thermometer of this type is extremely sensitive, and shows no appreciable lag when placed in a water bath; but when placed on the surface of the skin, it may take 15 minutes or more to reach a steady temperature.

Recording Instruments.—Two principal types of recording instruments are available, corresponding respectively to the deflection method and the balance method of measuring variations of electrical resistance. In the deflection method, the greater part of the resistance to be measured is balanced on a Wheatstone bridge by a balancing coil, and the small variations are observed by the deflection of the galvanometer. In the balance method, the galvanometer contact is moved along a bridge-wire until balance is obtained. This method is not so quick for small variations, but is generally most suitable for work with resistance thermometers, and has the advantage that the scale is uniform and independent of the E.M.F. of the battery. In clinical thermometry, the range of temperature to be covered is so small that the deflection method is generally applicable and the scale practically uniform. The scale is readily adjusted to read in degrees of temperature by means of a suitable rheostat in the battery circuit. If storage cells of sufficient capacity are employed there is little risk of error from variation of the E.M.F. of the battery. Thus, for clinical thermometry, there is little to choose between the balance and deflection methods, if the instruments employed in either case are equally sensitive.

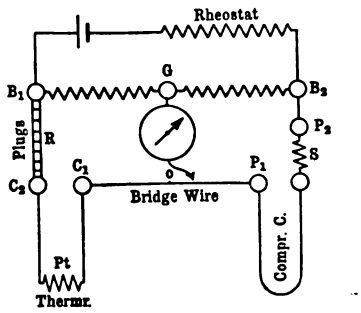

Fig. 4.—Diagram of Connections for Thread Recorder.

A practically continuous record may be obtained by the deflection method if the thread recorder of the Cambridge Scientific Instrument Co. is used. The standard type of thread recorder is a fairly robust instrument, having a resistance of about 10-12 ohms, and a scale of 80 mm. to 1 millivolt. With a copper constantan thermocouple this instrument gives a scale of about 3 mm. to 1°C., which is rather too small for clinical records. With a resistance thermometer, it is easy to get a scale of 50 mm. to 1°C. if desired, but a scale of 10 mm. to 20 mm. is usually sufficient. In using the thread recorder with a resistance thermometer, some form of platinum thermometer bridge with a slide-wire is required, and a rheostat or resistance box capable of fine adjustment between 30 and 50 ohms. This rheostat is connected in series with a 2 volt storage cell to the battery terminals, B, and serves to adjust the scale of the record. The thread recorder is connected to the terminals marked G on the bridge, one of which is connected between the equal ratio coils of 10 ohms each, and the other to the sliding contact on the bridge-wire, as shown in Fig. 4.

The two thermometer leads are *not* connected to the terminals marked P on the bridge (which is the usual arrangement when the balance method is used), but to the terminals marked C_1 C_2 (for compensator) so as to be in series with the adjustable plug resistances denoted by R in the annexed diagram of connections. The compensator leads are connected in series with the balancing coil denoted by S in Fig. 4, to the terminals marked P, P. With this arrangement the resistance S+C is nearly constant, so that if the galvanometer deflection is adjusted to be correct when the thermometer is at 0°C. or 20°C., or any convenient temperature, the scale will be very nearly correct when the thermometer is at any other temperature, the plugs R being suitably adjusted.

After describing the method of testing for defects and the calibration of the scale of the galvanometer, the author considers the balance method with the slide-wire recorder. This is the type of

Digitized by Google

recorder generally employed with resistance thermometers, especially where a large range of temperature is to be covered. It is equally applicable for clinical work, or for small ranges of temperature, provided that a suitable thermometer is employed, and that the current is properly adjusted to avoid excessive heating of the thermometer. It gives a strictly continuous ink record, with a pen attached to the sliding contact on the bridge-wire, which is automatically maintained at the balance point by means of a pair of motor clocks actuated by the deflection of the galvanometer. The galvanometer coil carries a light arm terminating in a contact fork consisting of two short platinum wires close together. A wheel with a platinum edge rotates between these two wires, one or other of which makes contact with the wheel (according to the direction of deflection of the galvanometer), and completes a relay circuit actuating one or other of the motor clocks. This form of relay is incredibly delicate, and has since been adopted by Brown for the purpose of submarine telegraphy. The scale of the instrument is independent of the E.M.F. of the battery, being determined by the resistance of the bridge-wire in relation to that of the thermometer. A recorder of this type is more expensive than the thread recorder, but is complete in itself, with the exception of the battery, and does not require either an auxiliary resistance box or a rheostat for adjusting the scale. It is a great advantage in practice that the scale never requires adjustment, but is always correct to about 1 in 1,000, provided that the bridge-wire is correct and uniform. For ordinary work thermometers are generally provided with an "ice-bobbin" or balancing coil, equal in resistance to the thermometer at 0°C. Some observers have experienced trouble with this type of recorder owing to the heating effect of the measuring current. Such troubles have arisen chiefly from the employment of unsuitable thermometers with excessive currents. With a 26 ohm thermometer the instrument can be adjusted to work perfectly on a scale of 4 cm. to 1°C. with a current of one hundredth of an ampere through the thermometer. The record can be read easily to less than a hundredth of a degree, or 1 in 30,000; and the heating effect of the current, with a celluloid thermometer of the surface type described, is only two or three thousandths of a degree, or practically inappreciable on the most open scale of the record.

The testing and adjustment of the slide-wire recorder are next dealt with by the author, who finally gives some interesting records which show that accurate clinical records of temperature on a fairly open scale under practical conditions may readily be obtained by the aid of electrical resistance thermometers, with either of the recording instruments above described.

POWER FOR ELECTROLYTIC COPPER REFINING.*

BY W. L. SPALDING.

Power is an important item in the cost of electrolytically refining copper. Per ton of product, it is less than in many electrochemical industries, since with soluble anodes the voltage factor of the power is used mostly in overcoming the ohmic resistance of an electrolytic and metallic circuit, and meets no opposing E.M.F. from decomposition of the electrolyte. Nevertheless, this item is in round numbers 40 per cent. of the cost of converting anode to cathode copper, or 20 per cent. of the cost, including furnace treatment. The relative amount, though not the actual, is increased by the extensive use of labour-saving machinery and mechanical handling of material. This use has been so far perfected that further reduction of costs must most easily be obtained through lower power charges.

In securing cheap power there are several considerations which greatly aid the refiner. First, the unchanging resistance and the continuity of the process allow a constant load day and night, and the steadiness and magnitude of the power used ensures the economy either of its generation at the plant or of its purchase from a power company. Secondly, waste-heat boilers on the reverberatory and cupola furnaces furnish considerable power at little expense, since the item of fuel is entirely eliminated from its cost, and were there a sufficient amount of it the refiner would not need to seek further. Its one disadvantage is its irregularity; for several hours during the day the furnaces are being dipped, charged or repaired, and furnish little steam, while for a couple of hours in the morning during poling they give a large quantity. The amount of this power available for electrolytic work depends, therefore, upon the material treated at the refinery, one commencing with pig copper or anodes receiving relatively a much smaller amount than one smelting ores or concentrates.

The purchase of electric power from a power company is very desirable electrically, and under some conditions is the most economical. If alternating-current power is received, the units for supplying the tank house circuits are synchronous motor-generator sets, which give a high efficiency of conversion, a 100 per cent. power factor, great facility of operation and regulation, and practically uninterrupted service. A refinery thus equipped should be the most favoured customer of the power company, as, with proper regulation, the load curve is absolutely flat, and no interest charge on machinery held in reserve can equitably constitute a portion of the rates. Moreover, the refinery may be used for filling up the valleys in the company's load curve, and the refiner may be able to contract for additional power at such times as the company directs for a figure lower than for his steady 24-hour load. It is true that the current-density will increase at these times, but as the deposition of copper can proceed satisfactorily under a wide range of current-density, this fluctuation is not open to the same objections as in processes that require a fixed minimum voltage or a constant supply of heat. A calculation of the saving from this cheaper power should involve the consideration that the cost of power per ton of copper is nearly proportional to the current-density, and too great an increase in the density will overbalance the lower rate. On the other hand, steps may be taken materially to lessen this increase. The tanks with insoluble anodes used for depositing excess copper from the electrolyte may be placed in circuit only at these times; each takes about eight times the energy of the ordinary tank, due to electrolytic decomposition, so that if their number is 2 per cent. of the total, their resistance is 14 per cent. of the total. A certain number of other tanks are also regularly short-circuited during the day for cleaning. Also it must be borne in mind that the current-density is proportional to the square root of the power, and hence its variation is less than that of the power.

In Buffalo, the cost of Niagara Falls power in lots of 500 H.P. or over is £5. 10s. per horse-power-year, which, converted to continuous current at 87 per cent. efficiency, equals £6. 3s., a surprisingly large sum for a region situated near a source of vast water-power. Unfortunately for the consumer, there is but one company owning a franchise in the city, and it has been able to keep the field free from rivals, and itself from adverse legislation. The price of power is, therefore, determined not by competition with other power companies, nor by cost of production, but by competition with steam power.

The refiner who wishes to use both waste heat and electric power for electrolysis is confronted by the interesting problem of combining the two so as to secure minimum cost per ton of output. The most satisfying way seems to be to supply a tank house circuit with two generators in parallel, one driven by a motor running on a constant amount of the purchased power, the other driven by a steam engine whose load varies with the steam. This arrangement permits the load to be divided in any ratio between the two generators by hand or automatic regulation of the shunt field rheostats, or the engine may be shut down on Sundays and during the dipping of the furnace charges when the supply of steam is not more than sufficient for driving air compressors or pumps and heating or evaporating the electrolyte. When the two loads are very different the equilibrium is delicate, but not disturbed. A series arrangement of the generators with half the circuit interposed between them would divide the voltage between the tank house terminals and decrease the current loss through earths, but excessive sparking due to the commutation of heavy current in a weak field would not allow the engine-driven generator to carry as small a load at periods of low steam. It is not economical to use the waste heat power on an independent circuit, as part of the time it would receive little or no current; the output of copper with a given power is proportional to the square root of the number of tanks and the electric power could be used to greater advantage if spread out over this circuit.

To determine the number of kilowatts to be bought for each month, a calculation of the amount necessary for the desired production should be made, the probable power from steam deducted, and the remainder maintained as a constant load on the motor. When the power paid for is the maximum two-minute peak occurring in the month, and these peaks are recorded by a graphic wattmeter, close regulation is essential. This can be obtained by hand regulation aided by a bell alarm, or, better still, by an apparatus that automatically changes the resistance of the shunt-field circuit of the generator when the wattmeter on the motor circuit records more or less than the desired quantity. With this attachment, the maximum two-minute variation from the average will be less than 5 kw. This combination of power necessarily gives a current-density greater at night than at day, but the fluctuation is not objectionable, and can be decreased as already mentioned. Further uniformity can be secured by using the peak of the steam for storing up heat in the electrolyte at night, and by rearranging the schedule of the furnaces so that their periods of dipping do not coincide.

The practicability of the use of electric power for refining copper has a direct bearing on a problem that is receiving considerable

* Abstract of a Paper read before the American Electrochemical Society.

Digitized by Google

attention in the industrial world—the problem of meeting, on the one hand, the demands of the electrochemical manufacturer for cheap power and, on the other, the desire of producers of electrical power to obtain customers who maintain a constant load, or who, better yet, can use large amounts of it at times when the rest of the producer's load is light. The magnitude of the scale on which electrolytic copper refining is now conducted makes the availability of cheap power an important consideration in the location of the refinery; and at the same time such a plant is an ideal customer for the power company. The existence of these common interests makes certain a mutual profit from their mutual recognition.

THE HIGH-TENSION NETWORK OF A GENERAL POWER SYSTEM.*

BY P. M. DOWNING.

Summary.—The author describes the experience of the Pacific Gas and Electric Co. with their extra high-tension transmission lines at from 20,000 to 100,000 volts pressure. The method of operation, transformers, switches, insulators, &c., are discussed.

This Paper is restricted to conditions as they have developed and as they exist in California at the present time, and to the experiences in connection with the different transmission systems, which together form probably the greatest mileage of high-tension network to be found anywhere in the world.

The system of the Pacific Gas & Electric Co. as it stands to-day represents the consolidation of a number of smaller companies, each with a system peculiar to itself. As a result, almost every type of apparatus is represented. This Company controls and operates 11 different hydro-electric generating stations, having an aggregate capacity of 64,270 kw. at generator pressures of from 500 to 5,500 volts. Ten of these stations have a common frequency of 60 cycles and run in parallel on a 60,000-volt network, which is also supplied with additional power from four independent companies. The Great Western Power Co. delivers 60,000 volts by stepping down from its main line voltage of 100,000; the Sierra & San Francisco Power Co., the Northern California Power Co. and the Snow Mountain Power Co. deliver current at 60,000 volts direct. At times the load carried by these four companies amounts to an aggregate of 41,500 kw. In addition there are steam and gas engine plants in reserve at three stations to a capacity of 21,500 kw.

The entire length of lines represented by the different systems which are tied together, exclusive of those of 11,000 volts and under, amounts to 1,920 miles. The voltages of the different lines making up the network are as follows: 150 miles of 100,000-volt line, 1,390 miles of 60,000-volt line and 380 miles of 20,000-volt line. Lines of 11,000 volts and under are not included in the above, as they are considered merely as distributing lines.

The paralleling of stations in this manner, regardless of the length of line between them, or the loads carried, has not developed any difficulties, but on the contrary it has been found that it could be done much more readily than where the generators are paralleled in the same station; nor is it customary to do this paralleling at generating stations alone, or on the low-voltage side of sub-stations. As a matter of fact, it is done almost entirely on the 60,000-volt side, using transformers of relatively small capacity connected from line to earth for synchronising purposes.

Operation.—The governing and the division of load between the different stations furnishing power to a system of this kind is not as great a problem as it would at first appear. Each station, excepting one, takes its alloted portion of load and makes no attempt whatever to govern, unless the frequency varies beyond certain predetermined limits, the speed control being left entirely to a single station. All important power houses are equipped with governors, which, except in the case of the governing station, are set so that they will be sluggish in their action, and will not operate except on wide variations of speed. Those in the governing station should obviously be adjusted to regulate as closely as possible. The governing is not limited to any one particular station, but it can be done at any station having sufficient capacity to handle the fluctuations of load.

In order to operate with a large number of stations running together we found it necessary to have a chief operator, or what we have seen fit to call a "load dispatcher," who, so far as the details of operation are concerned, is in absolute charge of the entire system. In his office there is a board showing diagrammatically every generating station transmission line and sub-station on the system, together with dummy switches representing every air and oil switch, and the exact position of these switches, that is, whether open or closed. In addition to the record as shown by the board, a very complete log is kept of every detail in connection with troubles of any kind, loads carried by the different stations, and any other matters pertaining to operation.

Telephone circuits are run on all transmission lines, but these are not depended upon for anything more than local use, such as for linemen reporting on and off the line, &c. They do not give satisfactory service when used over long distances, and they become inoperative when there is trouble on the line and when they are most needed. For communicating between important stations we have circuits leased from the telephone company, which run on its regular toll line leads, and being over entirely different routes are not affected to any extent by transmission troubles.

As stated above, the different stations are, for the greater part of the time, operated in parallel. There are two distinct advantages in operating in this manner: (1) The regulation of voltage is much more readily accomplished. (2) The capacities of the different stations can be utilised to their fullest extent. On the other hand, there is a distinct disadvantage, as trouble on any part of the system will, to a certain extent, affect the entire system.

The inductive drop on the long lines forming a network of this kind is obviously high, especially where the induction motor load is heavy and the power factor correspondingly low. The wattless current, therefore, becomes quite a problem, and has to be taken care of either by distributing it among the different power houses, or by taking it entirely on a single station, which can be handled very readily by proper adjustment of generator fields.

From an operating standpoint, and in order better to guarantee continuity of service to the more important districts, a reserve steam plant is very essential, and in this respect the modern steam turbine serves the purpose admirably. By reason of the fact that it operates equally well at all loads it can be connected in parallel with the transmission line, and under normal conditions will carry a good portion of the wattless current. At the same time it acts as a stand-by, and in case of line trouble it can pick up the load on very short notice.

Troubles on the long lines forming networks such as this do not always seriously affect the entire system, but show only as momentary drops in voltage. The station generators are connected directly to the line without circuit-breaking devices of any kind, and power is never cut off the lines unless it is impossible to keep it on. Immediately on the slightest indication of line trouble the system is separated, leaving different sections or districts supplied from different sources. If the trouble is far enough removed from the generating station it will not be very severe on account of the inductive and ohmic drop of the intervening lines, and generally the operators will have time to separate the sections without more than a temporary drop in voltage. If, however, the trouble is near a power-house, that particular station will be thrown out of synchronism with the system, and even the machines in that station may be thrown out of synchronism with each other.

The greater number of the lines feeding into the system are supplied from transformers delta-connected on the low-tension side and star-connected on the high-tension side with the neutral earthed. This arrangement has proved very satisfactory, and while it might be said that there is a disadvantage in using such a connection on account of the earthing of one wire throwing a short-circuit on the system, yet there is a question as to whether or not this is a real disadvantage. Where lines are run along public highways and through more or less thickly settled districts it seems almost necessary that there should be some very positive indication to show when a wire goes down.

Some objection has at different times been raised by the telegraph and telephone companies to an earthed neutral system, on account of the inductive influences due to curent through the ground, at times when the load is unbalanced. Experience, however, has shown that this is not the real cause of the trouble, but that the troubles these companies have are the result of what might be called static unbalance, or high-frequency disturbances due to arcing earths, or other causes which occur to a greater extent in an unearthed system than in one where the neutral is earthed, and therefore at zero potential. This statement is borne out by experiments.

Our usual practice is, where one of three transformers in a bank at the generating end is out of service, to carry load up to the capacity of the other two, or should occasion demand, to over-load the two, making them carry the normal load of the three. This same condition obtains in the case of step-down transformers. When the load to be supplied is small, and where the expense of installing three, or even two transformers to give a three-phase distribution would not be justified, it is customary to instal a single transformer, connecting it from the line wire to earth. Installations of this kind ordinarily give no trouble whatever, but work as satisfactorily as though a bank of three were installed. Careful attention must

*Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

always be given to the earth connection. These are made by connecting to the water mains, and also to earth plates buried to a depth depending on the character of the soil.

Occasionally it has been found where only a single transformer is used, that a severe static stress occurs on the low-tension side, which is severe enough to puncture the insulation of the lower voltage transformers supplied from the main transformer. These instances, however, have been comparatively few, and while it is something which might be expected from a connection of this kind, it very seldom occurs, and it has never been serious enough to make it necessary to abandon the practice.

The connection on the low-tension side of the step-down transformers is either delta or Y, depending entirely on the particular voltage condition to be met. Where the Y connection is used the neutral is earthed in the same manner as on the high-tension side, and to the same wire. So far as the actual operation of the system is concerned, there is no preference as to the connection on the low side, but for economic reasons the greater number of low-tension distributing systems are supplied from the Y-connected transformer. We have never yet had any troubles which we could trace back and find to be the result of the manner in which transformers were connected.

Transformers.—The capacities of transformers used range from 100 kw. to 1,500 kw. Most of them, except some of the smaller sizes, are shell type, oil-insulated and water-cooled. The most satisfactory case for oil-cooled transformers is one of boiler iron mounted on a cast-iron base and having a cast-iron top. The merits of the different insulating materials used in transformers for high-voltage work, the kind of oil to be used and the methods of cooling the oil have been much discussed. During the past few years the tendency of the transformer manufacturers has been toward the use of a press board or horn fibre for the insulating barriers between the coils, this material being used to replace the micanite used in the earlier transformers. This gives a transformer of lower first cost, but one correspondingly less staunch and reliable. The micanite insulation has two distinct advantages; first, it will not absorb moisture as readily as the pressboard or horn fibre; and second, being non-inflammable, it will localise trouble, and a burn-out in one coil, unless it be exceptionally bad, will not damage adjacent coils. Until a few years ago all of the transformers on the system had micanite insulation. They would be received from the factory, and without attempting to dry them out they would be filled with oil and put into service. The oil was generally shipped in iron drums containing from 50 to 100 gallons, and when received, it would be put into the transformer without treatment of any kind, and even without being tested to see that it had the proper dielectric strength. The pressboard has superseded the micanite, and the methods of handling transformers have entirely changed. We now find it necessary to dry them out thoroughly even after they have been standing without oil for not more than 10 days or two weeks. The oil also is being handled much more carefully than formerly, and separate samples taken from the different tanks in which it is shipped must be tested. If the dielectric strength is found to fall below a certain standard, it is safe to assume that the low insulating qualities are due to moisture, which can be readily removed by heating to a temperature slightly above 212° F.

The pressboard or horn fibre will not only absorb moisture from the atmosphere, but it will, when in direct contact with water, absorb sufficient of it to allow the layers of fibre making up the sheet to separate, thus rendering it worthless. This objection to its use might on first thought seem hardly worth considering, but in practice it is an important one. In handling transformers out of doors during stormy weather, or in the event of a damaged water coil allowing water to get into the winding, the pressboard would be damaged to such an extent that the transformer would have to be torn down and the barriers replaced.

As to the relative fire risks of air and oil-cooled transformers, I think it is now generally conceded that the oil type with a properly designed case is the safer of the two. The greatest danger from an oil-insulated transformer is from fire external to the transformer itself, which might damage the case and allow the oil to escape.

From the point of view of operation, particularly in connection with long high-voltage lines, I am inclined to question the advisability of attempting to sacrifice the reliability of the transformer in order to cut down the first cost. In the absence of any approved device or apparatus that can be relied upon to take care of high-voltage line disturbances, the transformer must bear this burden to a very great extent, and the breaking down of a transformer with the resulting interruption to service will in a very short time more than offset any saving in first cost. For this same reason the three-phase transformer is at a disadvantage, as trouble on one phase would entirely interrupt service unless a spare were installed.

For cooling the oil we employ the usual method of circulating water through copper coils immersed in oil. Different metals have been used in these coils, but on account of there being less liability of copper being acted upon by acids in the cooling water, and also because of the fact that it will not corrode, it has been found most satisfactory. In localities where there is any great amount of mineral in the water, a cooling coil will in time become filled to such an extent that it will not carry a sufficient amount of water to cool the transformer. This deposit closely resembles boiler scale, and in some instances it can be removed by taking the coil out of the case and hammering it on the outside to loosen the scale, after which it can be blown out by either steam or compressed air. In cases where it cannot be removed in this way we have used dilute muriatic acid as a last resort, but as this acts upon the metal of the coil, as well as upon the scale, it cannot be considered entirely satisfactory.

Periodic pressure tests are made on all cooling coils without removing them from the transformers, and very often without taking voltage off the transformer. This we do by disconnecting both ends of the coil and allowing the water in the lower turns either to drain off, or, if both ends of the coil come up over the case, a small rubber hose is inserted on the riser side of the coil and the water syphoned out.

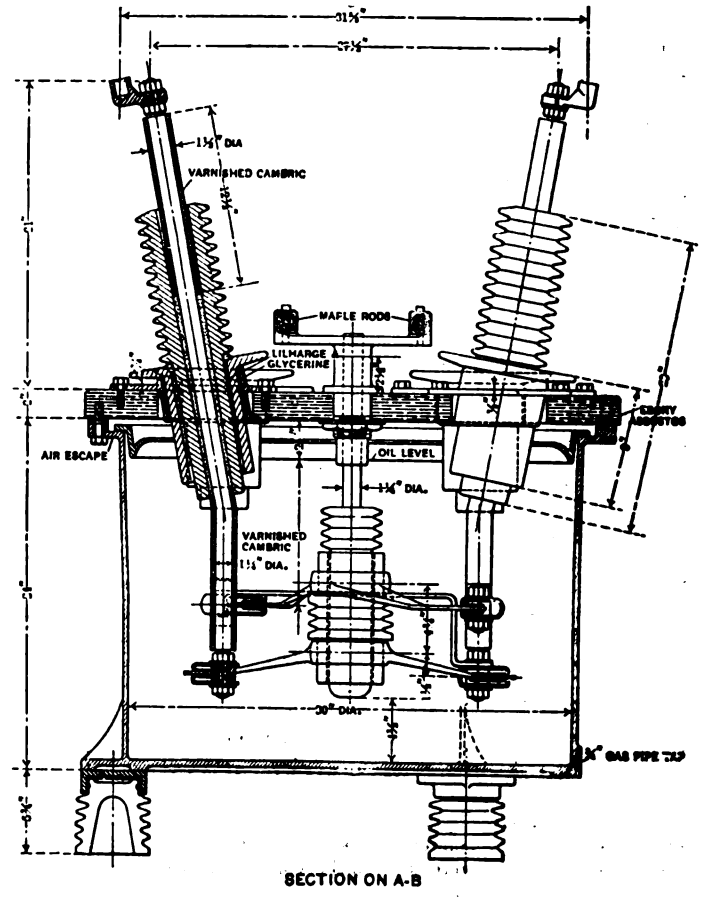

FIG. 1.—SECTIONAL ELEVATION OF HIGH-TENSION SWITCH.

To know that the coil is thoroughly dry, and that in the event of its breaking down under pressure no water will get into the transformer winding, a light blast of air is passed through the coil, which, with the heat from the oil on the outside of the coil, will in a very short time remove any moisture which might remain. One end of the coil is then plugged and air pressure applied by means of an ordinary automobile tyre pump. A small pressure gauge connected to the coil shows the pressure on the coil, and also whether or not there are any leaks which would allow the pressure to drop. Generally where there is no back pressure on the coils, 15 lb. to 25 lb. will be as high a test as is necessary.

Switches.—Outside of the lightning arrester or line discharger for taking care of high voltages, high-tension switches were probably slower to develop than any other piece of apparatus used in connection with long transmission lines. The system of the Pacific Gas & Electric Co. was one of the first to use oil switches for voltages in excess of 40,000. As early as 1900 we built and put into operation switches which were of practically the same type that we are now using. While the switch was in the experimental stages the framework supporting the tanks was of wood, and the tanks themselves were the ordinary fibre or paper mâche tubs such as are used for

Digitized by Google

laundry purposes. Switches of this kind served their purpose well, and are even now in use after years of service, but where they are called upon to break heavy loads, such as come on at times of short-circuit, they are apt to throw the oil out of the container when operated.

To overcome this trouble we designed a four-break switch along practically the same lines, but with a considerably greater depth of oil over the contacts. Four-break switches similar to that shown in Figs. 1 and 2 have been in service in some of our largest power-houses for several years, and they have never failed to open the line under all conditions of short-circuit. The particular features which recommend this switch are: (1) The absence of any insulating material that might become saturated with oil and catch fire either from leakage or from an arc. (2) The insulation of the switch from the ground, thereby affording the greatest protection against break-downs due to surges or other high-voltage disturbances when the switch is open. (3) A constant depth of oil over the contacts at all positions of the blades. (4) The comparatively small amount of space taken up by the switch.

We have never attempted to operate any of these high-tension switches either automatically or by any electric or pneumatic means, preferring rather to keep to the more positive hand-lever control. This control has generally proved quite satisfactory, but we have just installed some reverse current relays to be used in connection with the automatic operation of switches on lines which are connected together at both ends. We have yet to learn to just what extent these can be successfully employed, on account of the inherent weakness of alternating-current reverse-current relays, whose operation is dependent on both current and voltage, and the fact that in cases of severe trouble the voltage may drop so low that the relay will be inoperative.

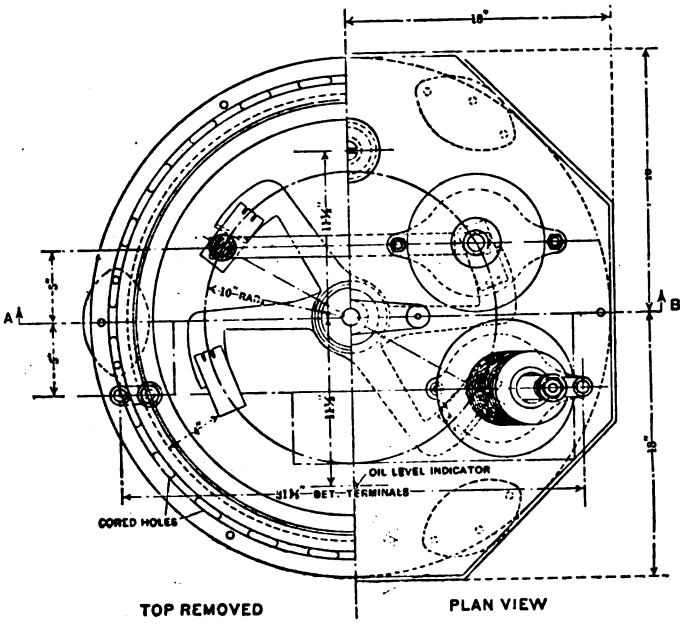

FIG. 2.—PLAN OF HIGH-TENSION SWITCH.

Lightning Arresters.—Except in the higher mountain districts, the Pacific coast is comparatively free from lightning, and we make no attempt whatever to protect against lightning disturbances. We use only the horn-gap type arresters with the air-gap set so that they will arc across on voltages approximately 25 per cent. above normal. The particular design of arrester used consists of two gaps in series with the earth side connected directly to earth without resistance. These are used more on account of their being voltage limiting devices than on account of their being a protection against high voltages. We do not instal them at every station, but only at the power-houses and more important stations where heavy switching is done.

Insulators.—The limiting voltage of a transmission system is at present governed by the insulators. The climatic conditions of the greater part of the Pacific coast are peculiar in that there are two seasons, one wet and one dry; and it may seem strange to say that the insulator trouble during the dry season, or just when the first rains start, is as much as or more than during the winter storms. The trouble is due to leakage over the surface of the insulator on account of the dirt and the salt which is deposited by the ocean fogs. As soon as the heavy rains come this accumulation of dirt, &c., is washed off, and the number of insulator troubles is materially reduced. The suspension insulator has a decided advantage in the fog district (where cleaning of pin insulators is necessary twice each year), in that a much greater part of the surface of the insulator is exposed to the rain and dirt is washed off during stormy weather. However, with the higher voltages at which this type of insulator is designed to be operated, there is every reason to think that similar troubles will be experienced, and doubtless the same homely means will sooner or later be resorted to in order to overcome it.

RESULTS OBTAINED AT THE BOULOGNE RADIO-TELEGRAPH STATION.

In a Paper read before the Société Internationale des Electriciens, A. Tosi gives a description of the new wireless telegraph station at Boulogne, together with some results of experiments which have been made there. The general appearance of the station and its aerial system can be gathered from the photograph already given in THE ELECTRICIAN of December 24, 1909 (p. 421). As regards the construction of the aerial, it suffices to say that in the present case, although for the Bellini-Tosi directive aerials pairs of inclined antennæ are used, the angle made with the vertical being about 32 deg., the distance between the tops of the aerials is now largely increased, being some 81 metres, as compared with 3 metres at the Dieppe experimental station. A further point is that the conductors joining the lower ends of the aerials are raised higher (4 metres) above the ground. The whole design thus approximates more nearly to what theoretical considerations indicate as being desirable. The station is fitted for working with the fixed wave-length of 300 metres for both the directive and the ordinary systems. A somewhat unusual method of working on the harmonic is employed, the natural wave-length of the directive aerial system being artificially increased so that it is three times as great as the wave-length used for signalling. For receiving, the ordinary system is used as a finder, or, in other words, for picking up signals, and the change over to the directive system is then made—by turning a switch handle—the security against interruption from ordinary or atmospheric causes being made greater with the directive method.

The results obtained as regards communication are stated to be excellent, messages having been regularly exchanged at night between Boulogne and Algiers, a distance of 1,500 km., using only ½ kw. of primary energy at Boulogne. It has been found that in all cases the signals received on the directive system—which is not earthed—are considerably stronger than those of the ordinary system. Some quantitative experiments made with a Duddell thermo-galvanometer at a distance of 3 km. from the station showed that, using the directive aerial, the deflection obtained is practically six times (113 : 19) as great as with the ordinary vertical antenna (earthed).

The concluding portion of the Paper makes mention of the use of the radiogoniometer on board ship for position finding. The author calls the radiogoniometer when used for this purpose a "wireless azimuthal compass," since it serves the same purpose as the standard compass.

In the course of a voyage to New York and back on the "Louisiane," of the Compagnie Générale Transatlantique, which was fitted with a temporary compass installation, it was proved that the useful range of the wireless compass was at least equal to that of the standard compass—namely, about 40 km. The bearings of several wireless telegraph stations as determined with the wireless and the standard compass were always identical. The important point was also established that the elevated metal parts of the vessel have no influence whatever on the bearing as determined with the wireless compass. The use of such a compass in time of fog is obvious, and is still further increased if a land station fitted with the directive method is available within range.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-second issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for August 19.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

DIELECTRIC LOSSES IN CABLES.

Cable makers have often been reproved in the past for the air of mystery which is said to surround their proceedings. Not that it is alleged that other manufacturers are any less secretive, but it has become a standing joke to affect an air of amused surprise when a cable maker takes part in any discussion at the Institution of Electrical Engineers. Why this should be so we do not pretend to know; we merely record the fact. If there are any mysteries connected with the art of cable making, there is no reason why anyone should be called on to disclose them. Probably the whole thing is a matter of accumulating experience, and no one can blame the man who refuses to give away his most valuable asset.

Still, the progress that has been made of late years in the matter of making cables has been very great. When one considers the raw material out of which the insulating medium is evolved, and the way in which these substances are liable to vary commercially, and the extraordinary difficulty of carrying out the process on a large scale, so as to get a product that shall be sufficiently uniform to stand the test of time and galvanometers, we can only feel satisfied that a good deal has been already learnt. It has almost certainly been learnt in some form or another by experience alone, in which the element of time has played a very important part; workshop test-rooms have probably taught something, but laboratory tests little or nothing.

However, there are certain important aspects of the problem on which light can only be thrown by galvanometers and oscillographs, and specially among these are matters that are referred to under the head of dielectric losses, though they have not so far produced results that are

Digitized by Google

capable of affecting the routine of the workshop to any large extent. It is not so many years since the question of dielectric losses was first mooted, only to be met with the derisive suggestion that the whole thing was a mare's nest. If we look back to the year 1901, when Mr. W. M. MORDEY read his Paper on the subject, it is easy to see what was then the state of knowledge on the subject. A very stormy discussion hinged on that Paper, but it led many to look a little deeper into the problem. Anyone who has had to do with the testing of cables knows that it is often accompanied with many perplexing incidents which need care for interpretation. After-thoughts and side-lights help one forward; but that man would be either very bold or very young who thinks that anything short of very prolonged work is sufficient to draw the veil from the many mysteries connected with the functions performed by the insulating cover of a high-tension cable. Without in any way depreciating the work which has been done in this country, it is only fair to say that a great deal of light has been thrown on the subject of dielectric hysteresis by the work which has been undertaken from time to time in the test rooms of the German makers. APT and MAURITIUS, on behalf of the Allgemeine Elektrizitäts Gesellschaft, in 1904 published valuable results; HUMANN in 1906, on behalf of Felten & Guilleaume, did the same; and Herr HÖCHSTÄDTER, working on behalf of the Siemens-Schuckert works in Berlin, in an investigation extending over more than six months, has now published his results, of which we give an abstract in our present issue. We think that this abstract will be read with great interest by those who have in any way studied the problem, and, if they do so, we think they are likely to agree with us in saying that it is no longer possible to reproach the manufacturer with any backwardness in the search for knowledge, or any disposition to hide from others, within certain limits, such things as he has found out.

When studying such a question as dielectric hysteresis great difficulty is experienced in the measurements owing to the low power factor. But they are not insuperable, as Herr HÖCHSTÄDTER and others have shown. His work is both interesting and important, owing to the fact that he has extended his researches to very high voltages, and has devised a very ingenious and successful method by which he has traced out the hysteresis loop, similar in all respects to the analogous case presented by the problems connected with the magnetisation of iron. He has applied voltages up to 60,000 and even more, and has continued up to the point at which the cable eventually breaks down under the electric stress. Some of his conclusions seem to differ from those of previous investigators. For instance, he asserts that the breakdown takes place suddenly; not, perhaps, so suddenly as to give no sign of impending dissolution, but so suddenly that if stopped just short of the point at which it is clearly seen that the cable is about to break down, it will after a short interval resume its normal state without trace of any internal change. Its insulation resistance and its capacity will then be found to be the same as before the test began. This is certainly a fact which has been alleged by some to be the case, whereas it has been disputed by others with good show of reason. Moreover, he states that he finds no trace of anything of the nature of a so-called viscosity or polarisation, and this, too, is to some extent contrary to the observations of some who have preceded him. HAWORTH, for instance, has stated that this is not the case with porcelain plates treated as a dielectric medium. It seems quite likely that no general statement can be made on this point, or perhaps on any other point, which applies generally to all types of insulating medium; and something may depend on the peculiarities of the particular substance under examination. Still, dielectric losses seem to be due to a kind of internal friction opposing electrification, whereas they were sometimes thought to be of the type of leakage losses, and to be traceable to the ohmic resistance of the insulation. But there is now a large accumulation of evidence to the effect that this is no true explanation of a loss which varies with the frequency.

Herr HÖCHSTÄDTER'S Paper indeed bristles with suggestive points, and not least of all should be mentioned that which is concerned with the choice of the most suitable frequency for a long transmission line if it should be proposed to use insulated cables. For many reasons it has of late years been found to be necessary or advisable to lower the frequency, and, if any further arguments are necessary, they may perhaps be found in the considerations that are bound up with the losses that are likely to take place in the transmission line in this case. The capacity of such a system of cables is very much greater than that of one making use of bare overhead wires, and the ohmic losses, due to the charging current, which are specially serious at times of light load, may become a factor of sufficient importance to merit attention. Further, there are matters connected with the measurement of the capacity of cables, and the discordant results which depend on the different methods of alternate-current measurement. It is now stated that the capacity, as measured ballistically, is exactly the same as that given by alternate-current methods if proper means are employed in the latter case, whereas the well-known formula, depending on effective volts and amperes, has long been known to give very variable results. This being so, it may help to explain some outstanding points, and to harmonise the disputes which have raged between earlier workers in the field.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Indiarubber and Gutta Percha. Translated from the French of T. Seeligmann, G. L. Torrilhon and H. Falconnet by JOHN GEDDES MCINTOSH. Second English Edition. (London: Scott, Greenwood & Son.) Pp. xvi. + 408. 12s. 6d. net.

The first edition was reviewed in our issue of August 28, 1903 (Vol. LI., p. 780), and this second edition does not seem to have benefited much by revision; on the contrary, the change from the direct to the oblique mode of quotation, where long extracts from the works of various authors or from patent specifications occur, has been so faultily effected that it is often difficult to decide on whom the responsibility for conclusions or remarks rests; while the bibliography has been omitted.

The English is very much of "the French as she is translated" order, and while the chemistry still remains in parts

Digitized by Google

"apalling" (the epithet of your former reviewer, than whom no one more capable to determine), the description of the mechanical plant is often bewildering even to the initiated, and must be incomprehensible to the ordinary reader; and the electrical portion displays throughout a lamentable want of acquaintance with the subject. The only method of testing dielectric resistance given is that with the electrometer by loss of charge, and this to be effected by Jenkin's "inferred zero" method of using the instrument, not, however, thus termed, and the description of which is unintelligible; and we would ask what are "Logarithms of the Resistance" tabulated in this fashion "1,973,959"?

The botanical and arboricultural sections are outside our domain.

The contents may be described as a compilation from a very large number of sources, existing mostly at the time when the manufacture of I.R. and G.P. was conducted on tentative and more or less experimental lines, long since abandoned. A small amount of more modern material has been drawn upon, as, for instance, Wright's Paper read before the Society of Arts (wrongly termed "Cantor Lecture") and Obach's Cantor Lecture, as well as Pontio's method of chemical analysis, which latter is based on the determination of certain constituents merely by differences, and can, therefore, hardly be considered as more trustworthy than that of Henriques, which is also described.

Unless, however, the reader have considerable acquaintance with the subject, and so knows how to refuse the evil and choose the good, we fear that he is here presented with a broken reed on which to lean if hoping for reliable information.

We had marked a few mysterious paragraphs for quotation, but we shall confine ourselves to one which stands without beginning of explanation, or end of comment, alone in all its simplicity (italics are in the original): "*Relative resistance* (after a minute of electrisation) *at different temperatures of ordinary gutta percha as cores in which the thickness of the gutta percha does not exceed* 2·79 *millimetres* ($\frac{1}{9}$ in.) (Willoughby Smith)."

The opinion of the vulcanisation of G.P. is thus expressed: "It will be well to pass the unfortunate experiments silently," and we propose thus to treat the further quotations from this "Complete Treatise," for such is the claim on the title page, but, alas! how little confirmed by the text! F. J.

Stromverteilung, Zählertarife und Zählerkontrolle b.i städtischen Elektrizitäts-werken und Ueberlandzentralen. Edited by CARL SCHMIDT. (Berlin: Julius Springer.) Pp. 99. M.2·60.

A great deal has already been published on distributing networks and methods of charging. Nevertheless, a book such as the present volume, which treats of the subject on lines representing the outcome of several years' practical experience, and from the point of view of the altered conditions due to recent progress and the extension of the system of distribution over wider and more scattered areas, forms a welcome addition to the literature of this branch of electrical engineering. Moreover, as the author himself points out in his preface, the results which are embodied in the book are in direct opposition to more generally accepted views. Within the small compass of the work it is not pretended that the whole question has been exhaustively dealt with.

The book is divided into two main portions, dealing respectively with current distribution and supply to consumers, and the main divisions are preceded by an introduction of a general character. The correct dimensioning of the feeders is briefly discussed, and then a number of numerical calculations are given for determining the voltage drop in lighting and power distributing mains, as well as in trolley wires and return rails for a tramway system, and the results are plotted graphically. Certain typical cases are then more closely investigated, with special reference to the voltage differences which occur in the most unfavourable case of a 5 H.P. motor being suddenly switched on in side streets, a corresponding higher consumption in the main streets and an overload of 50 per cent. in an individul route. The positions of feeder and transformer sub-stations are also dealt with, and the question of how to connect large consumers to the supply on the most advantageous lines is also carefully considered. These investigations are ably carried out, and are rendered clear by the aid of curves. Three-wire direct-current systems, alternating-current and three-phase networks are treated in this way. The first portion of the book concludes with examples on tramway feeders and return cables, and current distribution in bulk supply.

The second portion of the volume is on supply to consumers, tariffs and meter control. In a short review it is impossible to give an adequate idea of the contents. This part is divided into five sub-sections—generating and distributing costs, tariffs with capital charges and duration rebates, calculation of the receipts and expenditure in supplying current to small consumers, tariffs for small consumers, and tariffs for large consumers. In each case fully worked-out examples are given. The book is certainly one which deserves close study on the part of those engaged and interested in methods of electricity supply. H. G. S.

Das Elektrische Bogenlicht. By E. RASCH. (Brunswick: F. Vieweg & Sohn.) Pp. xxi. + 176. M6.

This is an extremely interesting book, giving in a concise form practically all that modern physics has to say about the electric arc. This information is carefully classified, so that the inventor or manufacturer can readily utilise it in any work on which he may be engaged. Each theory or physical fact is fully set forth, together with tables of constants or curves embodying recent experimental results where such are available, references being given in most cases to original Papers. The following examples may be given of its contents: Taking first the general theory, there is a clear statement of Schwedoff's ballistic theory of spark discharge, according to which a free ion moves in the electric field in a similar manner to that in which a lead ball falls under the action of gravity in a resistant medium. The curve given by this theory connecting sparking distance and P.D. shows the inflection near the origin obtained experimentally by Baille and Earhart. This theory is clearly explained without any skipping of the steps of the demonstration, and is accompanied by a table and curve giving a comparison of the results obtained by calculation with those obtained experimentally by four independent observers. Everything that is likely to be useful is discussed, *e.g.*, thermal conductivity and specific heat of mixtures of electrode materials, theories of light, &c.

As regards empirical matters, formulæ are given for the variation in the diameter of carbons with current for direct and alternating currents in open and enclosed arcs, including the diameter of the cores of cored carbons. Flame arcs, mercury vapour arcs and salted carbons are also discussed. The book is one of the well-known series "Elektrotechnik in Einzel-Darstellungen," edited by Dr. Benischke, of which the volume on "Illumination and the Emission of Light," by P. Högner, was noticed a short time ago in these columns. It should not be overlooked by any engineer interested in arc lamps who has a knowledge of German. It may be added that the style is clear and should not offer difficulty to those whose knowledge of that language is comparatively small.

The Aeroplane Portfolio. (London: Percival Marshall & Co.) 1s. net.

This portfolio contains nine scale drawings of the Farman, Voisin, Santos Dumont, Wright, Curtiss, Cody, Blériot, Antoinette and Rep aeroplanes, along with a pamphlet giving a short description of each, drawing attention to the chief characteristic points. The drawings are well done, and as the scale is generally in the neighbourhood of 4 ft. to the inch, a good deal of detail is shown. In each case the lift in pounds per square foot per horse-power is stated, but we should like to know on what the value of the horse-power is based. Unfortunately, its determination is generally very vague. It would add to the interest of the pamphlet if the author would in future include the weight of each aeroplane, the weight of the engine and the pounds per horse-power of engine. The portfolio will no doubt be welcomed by those interested in aviation, and we hope the author will keep it up to date, for progress is rapid in this new branch of engineering.

RECENT PHYSICAL RESEARCH.

III.—RUTHERFORD'S WORK ON THE α-PARTICLE.

BY DAVID OWEN, B.A., B.SC.

In the era of electrical research which one may conveniently date as beginning with the discovery of X-rays, one investigation has been by common consent singled out as a supreme intellectual and experimental achievement—namely, Sir J. J. Thomson's "counting" experiment, culminating in the estimate of the value of the charge of the electron, or negative unit of electricity. This result was announced in 1903. A second outstanding piece of work is that selected for the subject of this article, and embodied in two memoirs presented to the Royal Society in 1908. The first is entitled "An Electrical Method of Counting the Number of α-Particles from Radioactive Substances"; the second, "The Charge and Nature of the α-Particle." We may now accept the α-particles emitted by radioactive bodies, amongst which radium itself occupies the place of first importance, as consisting of rapidly moving particles of *helium* carrying a charge of positive electricity. If we denote this charge by the symbol E, using e to denote the numerical value of the unit negative electric charge, then, according to the above work of Prof. Ernest Rutherford, we have $E=2e$. The particles emitted by different radioactive bodies differ only in the speed of ejection. In their passage through matter they smash up or ionise the molecules in their path. In doing so they lose kinetic energy, and at a certain minimum velocity their ionising action ceases. The distance traversed, or the "range" of action, increases with the velocity (about one-tenth the speed of light) of initial projection. For example, in air at normal pressure the range of α-particles from radium emanation is 4·3 cm., whilst for those from radium C the range is 7 cm.

The determination of E involved two operations. Firstly, the actual counting of the number of particles emitted in a given time by a particular sample of radioactive matter; and, secondly, the direct determination of the charge carried by the same particles in the same time. The unique feature of Rutherford's work is the experimental method selected for the counting experiment, a method which was carried in his hands to a triumphantly successful conclusion.

It is well known that a screen of zinc sulphide when subjected to bombardment by a sample of radium shows scintillating points. This brilliant effect is plainly seen in the scintilloscope, and is now delightfully familiar. It was early observed that these scintillations were due to α-radiation, and not to β or γ-rays; and it was suggested that possibly there was one scintillation for every α-particle striking the zinc blende target. Rutherford's results establish this as a fact. In the scintillating point we have the visible effect of a single atom of matter, the helium atom, impressed with the enormously high velocity of its projection from a radioactive body.

The identification of the α-particle with the helium atom (with positive charge) has been carried by Rutherford to a remarkably direct test. The Papers already quoted, in conjunction with earlier work, lead to the result that the α-particle has a mass 3·84 times that of a hydrogen atom. The atomic weight of helium is known to be 3·96. The agreement of these numbers might be considered sufficiently within the probable limits of experimental error to warrant the deduction that the α-particle is identical with the helium atom. The direct experimental proof by Prof. Rutherford is in itself a further notable achievement. It will be found described in the "Philosophical Magazine" for February, 1909.

We will now proceed to consider the essential details of the crucial experiments referred to.

1. *Measurement of E.*—The determination of E consists in the measurement of the ratio

$$\frac{\text{total charge carried by a stream of α-particles}}{\text{number of particles in the stream}}.$$

Let us take first the method of determination of the denominator—that is, the "counting" experiment. The detectibility of the α-particle lies in the very great ionising power it possesses. It is estimated that in its passage through a gas, 46,000 ions are produced. Imagine these ions to be produced in the gas between a pair of parallel metal plates maintained at a steady difference of potential. The ions of one sign would be swept by the field into the plate of opposite sign. Thus, if one plate is insulated its charge would be instantly altered by 46,000 e for each α-particle shot between the plates, where e denotes the ionic charge. This amount lies just on the verge of detection by a sensitive Dolezalek electrometer. To enhance the effect a magnifying device was employed. Townsend has shown that the production of a spark by an electric field is due to the rapid generation of fresh ions which is caused by the collision with neutral molecules of the ions already present in the gas, and which, moving along the lines of the field, acquire the requisite amount of kinetic energy. For P.D.s much below the sparking P.D. only the negative ions are effective; but very near to the sparking P.D. the positive ions come into play, and likewise generate fresh ions. If, then, an α-particle be fired into the gas exposed to an electric field somewhat below the sparking value, each of the ions formed may in its turn generate fresh ions, multiplying in that proportion therefore the charge swept into each plate bounding the field. Such was the plan adopted by Rutherford. Each ion generated by the α-particle generated several thousands in its passage through the field.

Fig. 1 shows the apparatus employed. The radioactive preparation is placed in a very thin layer about 1 sq. cm. in area at D, centrally on the end of a hollow iron tube, P, which can slide along the interior of a glass tube, KL, 2·5 cm. in diameter and some 4 metres in length, one end of which is fitted with a diaphragm containing at its centre C a

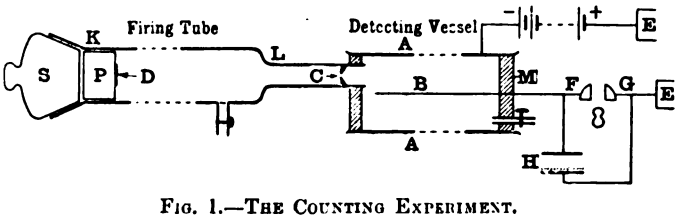

FIG. 1.—THE COUNTING EXPERIMENT.

hole of known size, about 1·5 mm. diameter, whilst the other end is closed by a ground glass stopper S. This tube we may call the *firing tube*. Connected to this tube, to the right of C, is a brass cylinder AA, closed by the ebonite stopper M, through which tightly passes a central wire B. The aperture at C is closed by a thin mica plate, which completely prevents the passage of gas between the chambers AA and KL. We may call AA the *detecting vessel*. The outer brass tube AA is connected to the negative pole of a secondary battery, the positive of which is earthed. The inner wire B is connected to one pair (represented by F) of the quadrants of a Dolezalek electrometer, the other pair being earthed.

Consider now the action in the detecting vessel and its connections. The contained gas is at a pressure of a few centimetres of mercury. Let the two pairs of quadrants of the electrometer be metallically connected. The electrometer needle will be at its zero position. Now remove the connection between F and G. The side F is insulated. Since between A and B is the electrical field produced by the battery, there will, even though the field is small, be a slight current through the gas from A to B. When the battery E.M.F. approaches the sparking P.D., this current will be much greater as already indicated. Thus the quadrants F will be charged up, and the needle will steadily move away from zero. By now placing in parallel with the quadrants a radioactive leak, consisting of a layer of a radioactive substance spread over the lower of a pair of plates, H, the upper one of which is insulated and in connection with F, this charge will produce a current in the ionised gas between the plates of H, tending to reduce F and G to the same potential. The needle will thus after a time acquire a position of equilibrium, at a deflection whose value can be conveniently controlled by the adjustment of H. If now an

Digitized by Google

α-particle pass through the mica window covering C into the detection vessel, the sudden increase of current from A to B will cause a ballistic throw of the electrometer needle, which will afterwards speedily resume its former position.

Consider, in the next place, the action in the firing chamber. A certain number of particles per second are flying off from the preparation at D. The average fraction that passes through the aperture at C may be calculated in terms of the distance between D and C, and the area of C. The actual number entering the detection vessel may be varied by altering the activity of the preparation at D, and by adjusting the distance between D and C, a magnet being used to draw the iron cylinder P along the firing chamber. Rutherford arranged that the number of particles entering the detection vessel should be on the average about three or four per minute, at which rate the superposition of the effects of two successive particles is avoided, and the ballistic throws can be counted with certainty. By this means, then, the number of particles leaving a radioactive preparation in one second could be accurately determined. The preliminary tests to determine the best conditions for accuracy, such, for instance, as the best dimensions of the chambers to employ, are here passed over. In order to avoid stoppage of α-particles between D and C the firing chamber was exhausted to a charcoal vacuum. The stopping power of the thin mica film across C was found and allowed for. The actual preparation employed at D was radium C, the α-particles of which escape with the same velocity. The amount of RaC is estimated by comparison with a standard sample of radium in radioactive equilibrium, whence the result can be finally expressed in terms of the number of α-particles emitted in one second by 1 gramme of radium in radioactive equilibrium. The number expelled from the RaC in 1 gramme of radium was found to be $3{\cdot}4 \times 10^{10}$ per second. There are three other α-ray products which each emit the same number of α-particles. The total number of α-particles expelled per second from 1 gramme of radium in radio-active equilibrium is therefore $13{\cdot}6 \times 10^{10}$.

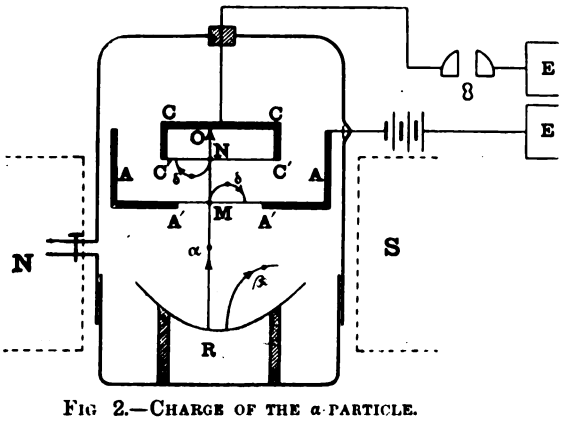

FIG 2.—CHARGE OF THE α PARTICLE.

There remains now the determination of the denominator, or the total charge of positive electricity carried by the stream of α-particles from the same RaC preparation; or, as in fact was the case, from a preparation of RaC whose strength is obtained by comparison with the standard sample of radium in precisely the same manner as in the counting experiment. The method of trapping the α-particles and of measuring their aggregate charge is one that had already been adopted with success by many workers, in the case of β- and cathode- as well as α-particles. A very brief outline only of this measurement will here be given. The cup R (*see* Fig. 2) is coated internally with a thin layer of the radioactive preparation. The thick metal box CC facing R is connected with one pair of quadrants of an electrometer, the other pair being earthed. R and CC are enclosed in a vessel in which a charcoal vacuum is produced. α- and β-particles leave R, and the latter are turned aside by the magnetic field between the poles N and S of a magnet. A calculable proportion of the α-particles leaving R will strike CC and be absorbed completely, giving up their charges. The attached pair of quadrants thus becomes charged positively, and the needle has a steadily increasing deflection from zero. The charge received is the product of the electrostatic capacity of CC (with its attached pair of quadrants), and the potential to which it has been raised. The measurement would be extremely simple if the vacuum were perfect. The α-particles, however, ionise the residual gas, thereby making it a conductor. The charge of CC would, therefore, leak away. To eliminate this effect a second metal plate, AA, is placed below CC, the central portion A′A′ being composed of a very thin sheet of aluminium. CC is likewise closed by a thin aluminium sheet C′C′. To AA one pole of a battery of a few cells is attached, the other pole being to earth. α-particles starting from R now reach CC after passing through the two thin plates A′A′ and C′C′, whose stopping power is comparatively small and calculable. If now, by means of the battery, CCC′C′ be given a potential which is negative with respect to AA, positive ions are carried into CCC′C′, whose positive charge, therefore, accumulates more rapidly than before. If, however, the poles of the battery be reversed the negative ions are swept into CCC′C′, which then gains positive electricity less rapidly than in absence of the battery. The mean rate of increase of the potential of CC measures the rate of reception of the charges of the α-particles alone. There is another disturbing element to be eliminated. When α-particles strike a metal, slow-moving β-rays, or δ-rays, as they are termed, are generated. Those forming at M have to be prevented from striking C′C′, whilst those generated at N have to be prevented from permanently leaving C′C′. The same magnet NS effects both these requirements. The diagram shows the slowly moving rays being bent into small circular orbits exactly as desired. (In Fig. 2, for diagrammatic simplicity, the orbits of the β and δ-rays are shown in the plane of the paper. Their planes are, of course, in reality perpendicular to the magnetic field.) The charge nE carried by n particles is thus measured. The counting experiment has supplied the value of n. The resulting value of the charge of the α-particle as given by Rutherford is

$$E = 9{\cdot}3 \times 10^{-10} \text{ E.S. units.}$$

The accuracy obtained appears to be high, of the order of 1 or 2 per cent. It is important to note that it is independent of the assumed radium content of the standard sample in terms of which the strength of the RaC preparation was determined.

2. *Mass of the α-Particle.*—It had for a few years been suspected that the α-particle is a positively charged atom of helium. Helium is invariably found in radioactive minerals, and in these alone. It has furthermore been directly proved, first in 1903, by Ramsay and Soddy, by aid of the spectroscope, that the radium emanation gives rise, in course of its transformation, to helium. Again, since the counting experiment gives the number of α-particles leaving a known quantity of radium in 1 second ($13{\cdot}6 \times 10^{10}$ per gramme per second for radium in radioactive equilibrium), knowing also the number of molecules per cubic centimetre of any gas at standard temperature and pressure ($2{\cdot}72 \times 10^{19}$), the rate of evolution of helium from radium may be theoretically calculated if we assume each α-particle to be a (charged) helium atom. The calculated quantity is 158 cubic mm. per year, or 0·43 cubic mm. per day. The actual amount has been determined directly by Sir James Dewar, the pressure of helium generated in a known space in a given time by a known quantity of radium being measured by the McLeod gauge. In experiments extending over 1,000 hours the rate of evolution of helium worked out at 0·48 cubic mm. per day. The agreement is very remarkable.

However, the above evidence does not necessarily prove that the helium actually consists of these aggregates of α-particles which have parted with their charge. As already stated, this point appears to have been satisfactorily set at rest by Rutherford's Paper of 1909.

The experiment is a very simple one. Radium emanation is enclosed in a very thin-walled glass tube, A (*see* Fig. 3), quite impervious to the emanation or to ordinary helium, but not to the rapidly moving α-particles. The surrounding vacuous space B may thus be examined spectroscopically for helium, utilising the capillary portion V of this space. The success of

Digitized by Google

the experiment was complete. The equilibrium quantity of emanation from 140 mg. of radium was compressed by a mercury column into the tube A, which had been drawn with walls only $\frac{1}{100}$ mm. thick, equivalent in stopping power to 2 cm. of air. B was initially exhausted to a charcoal vacuum. By raising the mercury column in B any gas present could be compressed into V, and the induction coil discharge made to pass. At first no trace of the helium line was to be seen; nor yet after 24 hours. In 48 hours the yellow helium line was visible; after four days the yellow and green lines of helium were bright, and after six days all the stronger lines of the helium spectrum were observed. Blank experiments were made to show that no helium was present in the glass or other parts of the apparatus. Helium gas was introduced into A, but no diffusion into B could be detected.

3. *The Natural Unit of Electricity.*—The question of the exact value to be assigned to the electronic charge cannot yet be regarded as settled. The value which has thus far been commonly accepted is that given by Sir J. J. Thomson—namely, $3{\cdot}4\times10^{-10}$ E.S. units. H. A. Wilson arrived at the value $3{\cdot}1\times10^{-10}$, whilst Millikan, also utilising the formation of drops by the condensation of aqueous vapour on negative ions, gave the number $4{\cdot}06\times10^{-10}$. Townsend, by a distinct method, concluded that the simple ionic charge is about $3{\cdot}0\times10^{-10}$. Boltwood's determination of the transformation constant of radium, combined with Rutherford's counting experiment, leads to $e=4{\cdot}1\times10^{-10}$. Perrin's estimate, from observations on Brownian particles, of the number of atoms in 1 gramme of hydrogen, leads to the value $4{\cdot}1\times10^{-10}$. Regener made observations on the α-particles emitted by polonium, counting with extreme care the number of scintillations produced on a zinc sulphide screen. This number was assumed to be equal to the number of α-particles emitted by the polonium. Combining this with a determination of the total charge carried by these particles, the value $9{\cdot}58\times10^{-10}$ was arrived at for E. By assuming $E=2e$, Regener finds for e the value $4{\cdot}79\times10^{-10}$. It should be added here that Rutherford has determined the number of scintillations produced by a radioactive sample, and at the same time the number of α-particles as obtained by the method of his "counting" experiment; and has discovered practically perfect agreement. For instance, in one experiment 294 scintillations were counted, this number proving to be 99 per cent. of the number given by the counting experiment. In a second, involving 150 scintillations, the ratio was 96 per cent. This experimentally observed agreement adds weight to the value obtained by Regener for e. Rutherford's experiments give E as $9{\cdot}30\times10^{-10}$, and this number is evidently one to which much consideration should be accorded in a revision of the value to be assigned to e. He accepts the view that the charge e carried by the hydrogen atom in the electrolysis of water is the fundamental unit of electricity, and that, therefore, E must be some multiple of e, either two or three. From considerations based on Boltwood's experiments, referred to above, he fixes upon the multiple two. Thus, for e he assigns the value $4{\cdot}65\times10^{-10}$. Finally, there is Planck's estimate of e based on thermodynamical considerations applied to radiation data, which lead to the number $4{\cdot}69\times10^{-10}$. It will be seen that the later values are distinctly higher than those first found. More work perhaps requires to be done before a revised value can be confidently chosen.

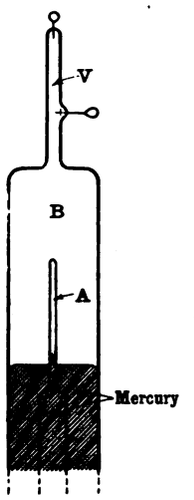

FIG. 3.—PROOF THAT THE α-PARTICLE IS AN ATOM OF HELIUM.

Telephones in Mines.—According to "Telephony," the Ohio General Assembly propose to enact a law compelling colliery owners to equip their mines with complete telephone systems. This has already been carried out in the state of Illinois and has proved of great service.

CORRESPONDENCE.

RAILLESS TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: So much interest is now being taken in England in the trackless trolley system, as shown by the articles lately published in your paper on the subject, that I am taking this opportunity to call your attention and also that of your readers to the Köhler Namag system. Although this system is the latest in the field (the patents being hardly a year old) it has made rapid progress in Germany. There is at present one line in operation and two others in course of erection which will be opened in a few weeks.

The new system differs in every main feature from the existing ones, as shown in the description given below. The overhead equipment consists of two hard drawn copper wires suspended one above the other in a vertical plane. The Köhler current-collecting device is a combination of the trolley wheel and the bow. The trolley wheels, two in number, run on the upper negative wire and the two bows are pressed against the lower part of the underlying positive wire by means of a spiral spring (Fig. 1).

The current is led to the vehicle by means of a flexible line which winds itself automatically on a drum mounted on the car, enabling this latter to behave on the road with the ease and freedom of a self-propelled vehicle. The current-collecting

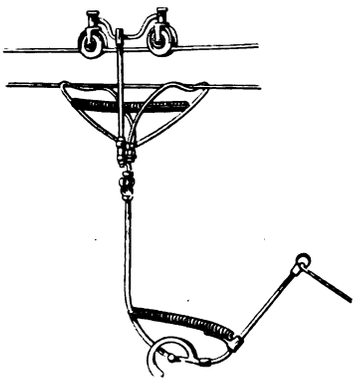

FIG. 1.

device is further fitted with an elastic articulation which guards the overhead system from the shocks which are caused by the sudden starting or stopping of the car.

The exceedingly small weight of the apparatus, combined with its ability to negotiate sharp curves, to adapt itself to the slightest movement of the car, and to operate in spite of differences in the sag of the two wires, all lead to light and cheap overhead work. It has the further advantage that it can be used without alteration for ordinary rail traction should increased traffic render this necessary.

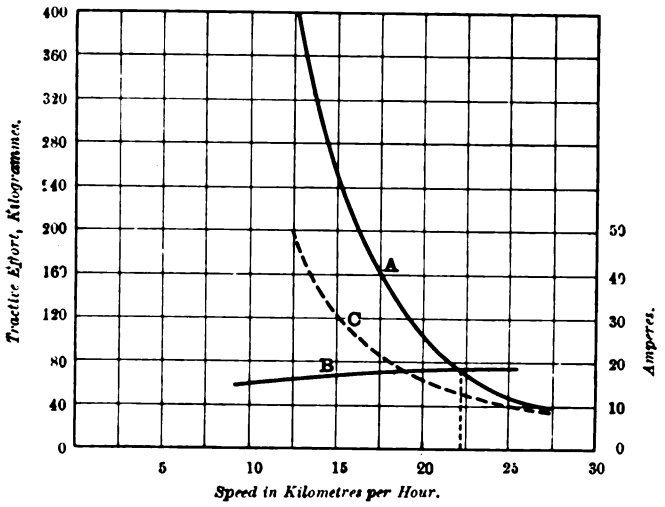
The cars are built by the Norddeutsche Automobile & Motoren Aktien Gesellschaft, of Bremen, which is well known on the Continent as one of the first makers of electric vehicles. It is interesting to note that they are similar in construction to the petrol cars of the same firm. The only change is that, in place of the engine and change-speed gear, an electric motor is rigidly mounted on the pressed steel chassis, and drives, through cardan and differential gearing, the rear wheels. There are two mechanical brakes and one electrical. The first mentioned are operated by foot pedals; one of them, the service brake, acts on the driven wheels, the other, the emergency brake, is mounted on the motor shaft.

According to prevailing conditions the motor is either an 8 H.P. or 14 H.P. moderate-speed continuous-current series motor, fitted with commutating poles. The main field is wound in two sections, thus permitting series parallel speed control (Fig. 2). The advantages of this construction are numerous. In the first instance, a moderate-speed motor realises the conditions of high efficiency, large starting torque

Digitized by Google

and overload capacity required in traction work. Its position just under the car flooring makes it easily accessible from all parts. Being rigidly fixed in the centre of the chassis, it springs with this latter and approaches the conditions met with in stationary work.

The controller is of the normal type for traction purposes, but is fitted with a special tripping device which breaks the current



A. Speed and tractive effort curve. B. Tractive resistance of 5-ton car (on level). C. Ampere speed curve.

FIG. 2.—CURVES FOR 8 H.P. 480 VOLT TRACTION MOTOR.

by operating one or other of the mechanical brake pedals. To establish the circuit again, the driver must first bring the controller to the neutral position.

The cars have seating accommodation for 20 people, and have also a back platform capable of holding four people. When fully loaded each weighs about 5 tons. The speed on the level under such conditions is about 23 km. per hour. Each car in addition can haul a trailer capable of accommodating 20 people (Fig. 3).

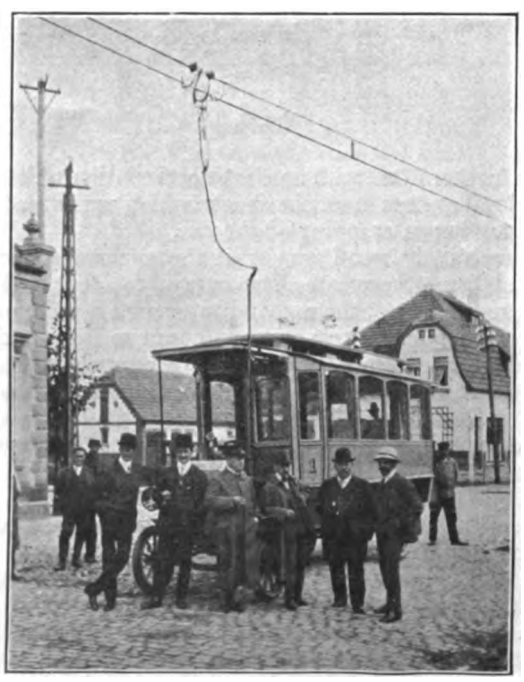


FIG. 3.

For freight transport the same company is building a heavy car with trailer capable of carrying 12 tons of goods at a speed of 10 km. per hour on level road. The construction is similar to the above; in this case, however, there is a double transmission, the motor driving through differential back gear on the rear wheels by means of chains and sprocket wheels.—I am, &c.,

Verviers, Aug. 24. P. A. MOSSAY.

THEORY OF THE QUADRANT ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Mr. Beattie's reply in your current issue to my former letter, allow me again to emphasise my points, as these seem to have been obscured. They are:—

1. Electrometer formulæ in which absolute potential appears as a factor, instead of the differences of these potentials, are irrational, because the phenomena depend on these differences only.

2. The electrostatic forces cannot, in general, be split into two portions of which one is independent of the position and the other proportional to the displacement. This may, of course, be true in some particular case, but the law connecting the force and displacement varies with the shape of the vanes and the quadrants, and also with their relative position at zero.

Like Mr. Beattie, I also deal with the forces acting, or the torques caused by these forces. Beyond the above two points, I think the only difference between us is that he uses a "k," whereas I, following the usual custom, express the k in terms of a well-known physical quantity.

A numerical factor of $\frac{1}{2}$ has inadvertently been omitted from the right-hand portion of the expression given in my letter for the total torque and of the denominator of the final equation. The absence of V_1 in this denominator is not an error. If $-dC_2/d\theta$ had been taken as a factor for the numerator, we should have had V_1 instead of V_2 below. By combining the two expressions the formula Mr. Beattie now gives can be easily obtained, which is rather more symmetrical than the one I gave, but at the same time more difficult to evaluate. It is also rational. When comparing Mr. Beattie's last formula with the one I gave, it should be noted that his convention as to the sign of $dC_2/d\theta$ is the opposite to mine.—I am, &c.,

DAVID ROBERTSON.

Merchant Venturers' Technical College, Bristol, Aug. 30.

BRUSSELS EXHIBITION FIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to the erroneous statements published in certain quarters, that the recent fire was due to electrical causes, and in view of the possible prejudicial influence this might have on electrical interests, your readers will be interested to know that I have the assurance of the engineer and director of the electrical department of the city of Brussels that the fire was not caused electrically.

Further, I am assured that the electrical supply in the buildings where the trouble started had been cut off some hours prior to the fire commencing.

My committee trust you will find space in your next issue for this letter.—I am, &c.,

H. B. RENWICK,

Chairman of the Electric Supply Publicity Committee.

London, Aug. 30.

INSPECTION AND INSURANCE OF ELECTRICAL AND OTHER MACHINERY.

The annual report of Mr. M. Longridge, chief engineer to the British Engine, Boiler & Electrical Insurance Co., always contains much of interest to electrical enigneers. In the report for the year 1909 it is mentioned that the breakdowns during the period under consideration were of less interest than usual, so that the descriptions of these occurrences have been curtailed, and the space thus made available has been filled by extracts from reports of trials made by the Company's engineers.

Dealing first with the breakdowns of machinery, we notice that these are considered under the usual headings, viz., (1) inspection and insurance of steam, gas, and oil engines; (2) inspection and insurance of electrical machinery; (3) insurance and inspection of boilers; (4) boiler explosions, collapses and sundry mishaps

Digitized by Google

In regard to the inspection and insurance of engines, the rate of increase of this branch of the Company's business was only about one-half the normal rate of a little over 6 per cent., the decrease being attributed to the state of trade generally. It is instructive to notice that the proportion of steam engines to gas engines insured has decreased from 27:20 to 26:20. The rate of breakdowns during 1909 was, among steam engines and turbines, 1 in 10·2 of the machines insured, and among gas and oil engines, 1 in 10·4, slightly lower in both cases than the figures of 1 in 9·4 and 1 in 9·1 respectively recorded in 1908, but slightly higher than those of 1907. The number of steam turbines insured is not yet sufficient to afford reliable information as to the ratio of breakdowns between this type of plant and steam engines. In steam engines, valves and valve gear continue to be the main cause of breakdown, the proportion of such failures being 34·1 per cent. of the total, compared with 34·8 per cent. in 1908 and 21·4 per cent. the average for 25 years previous to 1908. A considerable increase is shown in the number of breakdowns attributed to the failure of air-pump buckets and valves, the percentage of the total breakdowns being 10·7, as against 6·2 per cent. a year ago and 7·2 per cent. the average of the previous 25 years. In the case of gas and oil engines, valves and valve gear accounted for 29·6 per cent. of the total number of failures, compared with 31·3 per cent. in 1908, whilst gas producer plants seem to be increasingly unreliable, the percentage of failures of this part accounting for 11·4 per cent. of the total number of failures, the figure last year being only 3·0 per cent., and 0·5 per cent. for the previous 25 years. It is instructive to notice the causes of the breakdowns as set out in the following table :—

—	Steam engines.	Gas and oil engines.
	Per cent.	Per cent.
Accidents and causes unascertained	27	34
Old defects or deterioration by wear and tear	41	19
Weakness, bad design, workmanship, or material.	18	23
Negligence of owners or attendants.....	14	24
	100	100

In regard to these percentages Mr. Longridge remarks : The number of breakdowns of steam engines attributed to old defects and wear and tear is unusually high, and, as the number assigned to accidents and causes unascertained is little below the normal, it follows that the numbers due to weakness, bad design and negligence must be unusually low. A few years ago the writer (Mr. Longridge) remarked on the evidence of improved design and workmanship furnished by the analyses of breakdowns of insured engines. The analysis for 1909 supports the view that technical education and foreign competition are influencing British methods of design. The decline in the number of casualties resulting from neglect is also satisfactory. In regard to gas engines, the large percentage of breakdowns from unknown causes is unsatisfactory, but difficult to alter, because so many of the gas engines insured are small, and on the occurrence of a breakdown are either repaired or dismantled for repair before the inspector can examine them. The cases of weakness and bad design are also rather numerous. The weakest parts are undoubtedly the crank-shafts ; as many as 13 per cent. of the breakdowns for the year were breakages of shafts. Has not the time come to build these parts instead of forging them in a single piece ? That about one-fourth of the breakdowns resulted from neglect, arises from the practice of leaving small gas engines without skilled attendants, or without attendance altogether. Typical examples of steam and gas engine failures are given in the report.

Turning to the second part of the report, dealing with the electrical branch of the Company's business, the rate of increase in new business in this section has been affected by the state of trade. It is very satisfactory, however, to learn that the rate of increase in the number of breakdowns is much less than in previous years ; in fact, fewer breakdowns of dynamos were recorded than in 1908. The cost of repairing the damage done was also less, except in the case of starting switches and controllers. The rates of breakdown among the various classes of machines were as follows : Dynamos—continuous current 1 in 17·2, alternating current 1 in 17·5 (1 in 13·7 and 1 in 5·7 respectively in the previous year) ; motors—continuous current 1 in 8·2, alternating current 1 in 9·5 (1 in 9·2 and 1 in 11·3 respectively in the previous year) ; starters and controllers—1 in 25 (1 in 24 in the previous year). The proportion in which the various parts of the machines caused or initiated the breakdowns are tabulated below, with the figures for 1908 and the averages for the preceding seven years :—

Parts believed to have failed first.	Dynamos.			Motors.		
	1901–7	1908.	1909.	1901–7	1908.	1909.
Armatures & rotors, per cent.	57·3	30	40	51·4	36	37
Commutators and „ slip rings.	20·0	40	29	22·0	26	27
Magnet coils and „ stators.	8·6	11	12	13·6	16	20
Brush gear and „ terminals	...	...	3	...	5	4
Shafts, spiders, cores, „ binders, pulleys, and gear wheels.	14·1	11	12	13	9	7
Frames, pole pieces, „ bearings, &c.	...	8	4	...	8	5
	100·0	100	100	100·0	100	100

STARTING SWITCHES AND CONTROLLERS.

—	1905-7.	1908.	1909.
Resistance coils .....per cent.	52·0	52	52
Contacts and switch arms ..... „	11·0	10	9
Automatic apparatus ..... „	14·4	13	21
Frames, slabs, carriers for coils, springs, &c. „	22·6	25	18
	100·0	100	100

As a large majority (85 per cent.) of the machines insured are motors, it may be interesting to tabulate the figures for the last two years for continuous and alternating current motors separately as under :—

Part which is believed to have failed first.	D.C. motor.		A.C. motor.	
	1908.	1909.	1908.	1909.
Armatures or rotors.....per cent.	38	39	21	23
Commutators or slip rings ..... „	29	31	2	6
Magnet or stator coils..... „	11	15	53	49
Brush gear and terminals ..... „	6	3	...	8
Shafts, spiders, cores, binders, „ pulleys, gear wheels, &c.	9	7	6	6
Frames, pole pieces, bearings, &c. „	7	5	18	8
	100	100	100	100

The causes of the above breakdowns are believed to be as follows :—

—	Dynamos.		Motors.		Starters.	
	1908.	1909.	1908.	1909.	1908.	1909.
Accidental .....per cent.	6	5	4	2	8	5
Dirt and neglect... „	23	20	30	26	17	19
Age and deterioration „	25	16	20	14	25	17
Bad work or design „	20	23	11	14	9	14
Overloading ..... „	...	1	1	1	2	2
Unascertained .... „	26	35	34	43	39	43
	100	100	100	100	100	100

The following typical examples of breakdowns selected from the report will probably prove of interest :—

1. Four-pole series-wound 16½ H.P. motor, 2 years old, receiving current at 440 volts from the two outer wires of a three-wire continuous-current system, with the middle wire earthed. The motor was attached to a 4 ton stationary jib crane. One of the Company's inspectors was sent for to find out why the craneman got a shock, as he averred he did, when he put his foot on the brake. The inspector found that when the man, standing with one foot on the ground, put his other foot on the

Digitized by Google

brake, he at the same time pressed with his knee one of the cables from the controller to the motor against the edge of an iron bracket which carried the supply cables. The rough edge of the bracket had gradually worn away the insulation which had previously guarded the copper conductor from the iron. Consequently, when the man pressed the cable against the bracket, the bracket, the crane, and the man's body formed a 220 volt circuit between the outer and the earthed middle wire of the supply. The moral is that all the ironwork of the crane should have been efficiently earthed.

2. Three-phase alternating-current motor, 4 years old, with wound rotor fitted with slip rings, giving 350 H.P. at a speed of 195 revs. per min., with current at 500 volts. The motor was coupled by spur gearing to the crank shaft of an old hauling engine, from which the connecting rod had been uncoupled. Its speed was regulated by a controller of the barrel type, immersed in oil, which cut in or out resistances in the rotor circuit. The motor and controller were placed in the engine-room below ground, close to the down-cast shaft, and separated from the up-cast by wooden doors. The room had a wood floor, and was surrounded by virgin coal. Owing to some defect, possibly a short-circuit between contacts of different phase within the controller, the oil in the box and the resistance cables leading from it were set on fire. The heat was sufficient to vaporise the oil, which burnt furiously and set fire to the doors dividing the up-cast from the down-cast shaft, thus short-circuiting the ventilation of the pit. The sand provided for the extinction of fires, in accordance with special rules issued in 1905 for the installation and use of electricity under the Coal Mines Regulation Act of 1887, was useless, as it would not smother a vertical or suspended cable, but the fire was put out before the coal became ignited. Whether one of the chemical extinguishers would be effective in such a case remains to be proved, but at first sight it would seem more promising than sand.

3. Three-phase alternating-current 12-pole induction motor, built in 1907, to give 350 B.H.P. at 500 revs. per min., with current at 11,000 volts per phase, frequency, 50 per second. The stator winding consisted of 5,760 No. 13 S.W.G. double cotton-covered and braided copper wire conductors, distributed in 144 tubes of insulating material carried in as many partly-closed slots, so that each slot held a tube containing 40 conductors. The stator was probably wound by the "pin" method; that is, each tube was filled with 40 steel wires, which were drawn out one by one to allow of the winding being threaded through the space left by the withdrawal. The winding was divided into 18 coils, six coils per phase, star-connected, so that the voltage between each terminal and the neutral point was 6,360, and between each coil 1,060, under normal working conditions. The rotor was of the wound type, with three slip rings and brush gear for connection to a variable liquid resistance for starting. There was no starting apparatus in the stator circuit beyond a three-pole oil-immersed switch, without any impedance, inductive or otherwise, between the supply and the motor terminals. The motor was coupled to and drove a continuous-current dynamo, giving 478 amperes at 500 volts. It was first insured in July, 1907. The stator windings repeatedly broke down, first one and then another of the coils nearest the terminals giving way by short-circuiting on themselves. One of these failures occurred inside one of the insulating tubes above mentioned, the rest outside. It was at first thought that the breakdowns were due to concentration of potential across the coils at starting, and then that the failures were due to "surging" or resonance effect from disturbances in the supply cables, but the Company could find no evidence to support the theory. An examination of a damaged coil in July, 1909, however, gave a clue. The cotton covering was bleached, stained green, and absolutely rotten. A test with litmus paper showed it to be acid, and analysis proved the acid to be nitric acid. The Company, therefore, came to the conclusion that the cause of the repeated breakdowns was the destruction of the insulation by nitric acid formed by decomposition of the air by brush discharge from the high-tension conductors, the result of the electrostatic action being the production of a compound, N_2O_5, which, in combination with the moisture in the air, is changed into nitric acid according to the formula $N_2O_5 + H_2O = 2\,HNO_3$. The reasons why the coils nearest the terminals were specially affected are: (1) The difference of potential is highest at these parts of the windings, and the brush discharge and formation of nitric acid greatest; (2) concentration of potential, which in this case no doubt broke down the rotten insulation, is bound to occur more or less across the terminal coils at starting.

Unless brush discharge can be sufficiently reduced, as has been claimed, by restricting the conductors in each slot of the stator to a single row, laid one on top of each other, the only way of preventing damage seems to be to insulate the conductors completely from air and moisture. This may be done by using formed coils thoroughly impregnated and made up solid with waterproof materials before being placed in the slots. Unfortunately this method involves open slots in the stator core, which are detrimental to induction motors, especially small ones, both as regards efficiency and power factor on the one hand, and weight and cost on the other. It has not been found practicable thoroughly to impregnate windings after being placed in position. Adequate protection can, however, be obtained for conductors wound by the "pin" method by placing them in waterproof tubes projecting beyond the ends of the slots in the stator core, and binding the projecting portions and the end windings emerging from them with a thick covering of tape saturated in some adhesive and waterproof material, to seal them completely from air and moisture. Had this been done in the present case the motor would no doubt have run satisfactorily on the 11,000 volt supply, but the makers preferred to alter and rewind the machine for 440 volts, and to supply a step-down transformer, rather than risk further trouble from the higher voltage, and to this the owner of the motor agreed.

Mr. Longridge concludes this section of the report by reminding all who have to clean or inspect high-tension machinery that when insulated and endowed with large electrostatic capacity it will conserve a charge for a considerable time after current has been switched off. No one should therefore, Mr. Longridge remarks, attempt to handle any part until he has satisfied himself that it has been completely disconnected from the source of supply for a sufficient time, say, 10 minutes, and the part before being handled should be always touched lightly and quickly with the finger.

The increase of 4¾ per cent. in the number of boilers under inspection is considered very satisfactory, having regard to the rate at which small steam engines are being supplanted by gas engines and electric motors.

After referring to the Board of Trade reports on boiler explosions and mishaps of various kinds, the testing of the discharge of a turbo blower is described.

An extract from the report of the test of a 500 kw. exhaust steam turbo-generator is also given: The machine was put down to generate three-phase current at 550 volts, with the exhaust steam from a pair of winding engines, supplemented when necessary by steam from the boilers, reduced in pressure by a reducing valve. The turbine was of the impulse type, and ran at 1,500 revs. per min. During the trial the exhaust from the engines was not used, but steam was supplied at an average pressure of 129 lb. by two Lancashire boilers. The exhaust from the turbine was led into a barometric condenser. Near the turbine the steam passed through a reducing valve said to be set at 1 lb. above atmosphere, and in passing through the throttle valve the pressure was further reduced to 10·5 lb. absolute or about 4·25 lb. below atmosphere.

Assuming the specific heat of superheated steam to be 0·5, the superheat due to the fall of pressure from 129 lb. gauge pressure or 144 lb. absolute pressure to 10·5 lb. absolute pressure, would be $(1{,}222 - 1{,}173) \div 0{\cdot}5 = 98°$ F. The actual superheat shown by a thermometer in a mercury cup between the throttle valve and the turbine was 78 deg., the missing 20 deg. of superheat being only sufficient to evaporate 1 per cent. of the feed water, even if no heat were lost by radiation. It is, therefore, clear that practically the whole of the steam condensed in the steam range was drawn off by the drains and steam traps.

The steam consumption per kilowatt-hour worked out, over a 7 hours' test, at 40 lb. It would, of course, have been higher if the turbine had been driven by the exhaust steam from the engines, as this steam would not have been superheated.

Mr. Longridge's report concludes with an abstract from some tests on a horizontal compound tandem engine.

PROF. HOBSON'S ADDRESS TO SECTION A OF THE BRITISH ASSOCIATION.*

Reference is first made to the death of Sir William Huggins, one of the most illustrious of the British workers in science during the nineteenth century.

The names of the great departments of science, mathematics, physics, astronomy, meteorology, which are associated with Section A, are a sufficient indication of the vast range of investigation which comes under the purview of our section. An opinion has been strongly expressed in some quarters that the time has come for the erection of a separate section for astronomy and meteorology, in order that fuller opportunities may be afforded than hitherto for the discussion of matters of special interest to those devoted to these departments of science. I do not share this view. I believe that, whilst the customary division into sub-sections gives reasonable facilities for the treatment of questions interesting solely to specialists in the various branches, a policy of disruption would be injurious to the wider interests of science. It appears to me unwise, in view of the general objects of the British Association, to give too much prominence in the meetings to the more technical aspects of the various departments of science. Ample opportunities for the full discussion of all the detailed problems, the solution of which forms a great and necessary

* Abstract of the presidential address delivered by Prof. E. W. Hobson, Sc.D., F.R.S., at Sheffield yesterday.

Digitized by Google

part of the work of those who are advancing science in its various branches, are afforded by the special societies which make those branches their exclusive concern. The British Association will, in my view, be performing its functions most efficiently if it gives much prominence to those aspects of each branch of science which are of interest to a public at least in some degree larger than the circle of specialists concerned with the particular branch. To afford an opportunity to workers in any one department of obtaining some knowledge of what is going on in other departments, to stimulate by means of personal intercourse with workers on other lines the sense of solidarity of men of science, to do something to counteract that tendency to narrowness of view which is a danger arising from increasing specialisation, are functions, the due performance of which may do much to further that supreme object, the advancement of science, for which the British Association exists.

I propose to address to you a few remarks, necessarily fragmentary and incomplete, upon the scope and tendencies of modern mathematics; and not to transgress against the canon I have laid down, I shall endeavour to make my treatment of the subject as little technical as possible. Probably no other department of knowledge plays a larger part outside its own narrower domain than mathematics, some of its more elementary conceptions and methods having become part of the common heritage of our civilisation, interwoven in the every-day life of the people.

The concepts of the pure mathematician, no less than those of the physicist, had their origin in physical experience analysed and clarified by the reflective activities of the human mind; but the two sets of concepts stand on different planes in regard to the degree of abstraction which is necessary in their formation. Those of the mathematician are more remote from actual unanalysed precepts than are those of the physicist, having undergone in their formation a more complete idealisation and removal of elements inessential in regard to the purposes for which they are constructed. This difference in the planes of thought frequently gives rise to a certain misunderstanding between the mathematician and the physicist, due in the case of either to an inadequate appreciation of the point of view of the other. On the one hand it is frequently and truly said of particular mathematicians that they are lacking in the physical instinct; and on the other hand a certain lack of sympathy is frequently manifested on the part of physicists for the aims and ideals of the mathematician. The habits of mind and the ideals of the mathematician and of the physicist cannot be of an identical character. The concepts of the mathematician necessarily lack, in their pure form, just that element of concreteness which is an essential condition of the success of the physicist, but which to the mathematician would often only obscure those aspects of things which it is his province to study. The abstract mathematical standard of exactitude is one of which the physicist can make no direct use. The calculations in mathematics are directed towards ideal precision, those in physics consist of approximations within assigned limits of error.

There exists a widespread impression amongst physicists, engineers and other men of science that the effect of recent developments of pure mathematics, by making it more abstract than formerly, has been to remove it further from the order of ideas of those who are primarily concerned with the physical world. The difficulty of obtaining an adequate notion of the general scope and aims of mathematics, or even of special branches of it, is perhaps greater than in the case of any other science. Many persons, even such as have made a serious and prolonged study of the subject, feel the difficulty of seeing the wood for trees. The severe demands made upon students by the labour of acquiring a difficult technique largely accounts for this; but teachers might do much to facilitate the attainment of a wider outlook by directing the attention of their students to the more general and less technical aspects of the various parts of the subject, and especially by the introduction into the courses of instruction of more of the historical element than has hitherto been usual. All attempts to characterise the domain of mathematics by means of a formal definition which shall not only be complete, but which shall also rigidly mark off that domain from the adjacent provinces of formal logic on the one side and of physical science on the other side, are almost certain to meet with but doubtful success. Such definitions, many of which have been advanced, are apt to err by excess or defect, and often contain distinct traces of the personal predilections of those who formulate them. Perhaps the least inadequate description of the general scope of modern pure mathematics—I will not call it a definition—would be to say that it deals with *form*, in a very general sense of the term; this would include algebraic form, geometrical form, functional relationship, the relations of order in any ordered set of entities such as numbers, and the analysis of the peculiarities of form of groups of operations.

The belief is very general amongst instructed persons that the truths of mathematics have absolute certainty, or at least that there appertains to them the highest degree of certainty of which the human mind is capable. It is thought that a valid mathematical theorem is necessarily of such a character as to compel belief in any mind capable of following the steps of the demonstration. Any considerations tending to weaken this belief would be disconcerting and would cause some degree of astonishment. At the risk of this, I must here mention two facts which are of considerable importance as regards an estimation of the precise character of mathematical knowledge. In the first place, it is a fact that frequently, and at various times, differences of opinion have existed among mathematicians, giving rise to controversies as to the validity of whole lines of reasoning, and affecting the results of such reasoning; a considerable amount of difference of opinion of this character exists among mathematicians at the present time. In the second place, the accepted standard of rigour—that is, the standard of what is deemed necessary to constitute a valid demonstration—has undergone change in the course of time. Much of the reasoning which was formerly regarded as satisfactory and irrefutable is now regarded as insufficient to establish the results which it was employed to demonstrate. It has even been shown that results which were once supposed to have been fully established by demonstrations are, in point of fact, affected with error.

The author next explains in general terms how these phenomena are possible. A set of data ideally perfect in respect of precision and permanence is unattainable—or at least has not yet been attained; and the adjustment of frontiers is one of the most frequent causes of strife. As a matter of fact, variations of opinion have at various times arisen within the ranks of the mathematicians as to the nature, scope and proper formulation of the principles which form the foundations of the science, and the views of mathematicians in this regard have always necessarily been largely affected by the conscious or unconscious attitude of particular minds towards questions of general philosophy. It is in this region, he thought, that the source is to be found of those remarkable differences of opinion amongst mathematicians which have come into prominence at various times, and have given rise to much controversy as to fundamentals.

Both in geometry and in analysis our standard of what constitutes a rigorous demonstration has in the course of the nineteenth century undergone an almost revolutionary change. That oldest text-book of science in the world, "Euclid's Elements of Geometry," has been popularly held for centuries to be the very model of deductive logical demonstration. Criticism has, however, largely invalidated this view. It appears that, at a large number of points, assumptions not included in the preliminary axioms and postulates are made use of. The fact that these assumptions usually escape notice is due to their nature and origin. Derived as they are from our spatial intuition, their very self-evidence has allowed them to be ignored, although their truth is not more obvious empirically than that of other assumptions derived from the same source which are included in the axioms and postulates explicitly stated as part of the foundation of Euclid's treatment of the subject. The method of superimposition, employed by Euclid with obvious reluctance, but forming an essential part of his treatment of geometry, is, when regarded from his point of view, open to most serious objections as regards its logical coherence. Physicists and others often maintain that the modern extreme precision amounts to an unnecessary and pedantic purism, because in all practical applications of mathematics only such functions are of importance as exclude the remoter possibilities contemplated by theorists. Such objections leave the true mathematician unmoved; to him it is an intolerable defect that, in an order of ideas in which absolute exactitude is the guiding ideal, statements should be made, and processes employed, both of which are subject to unexpressed qualifications, as conditions of their truth or validity. The pure mathematician has developed a specialised conscience, extremely sensitive as regards sins against logical precision. The physicist, with his conscience hardened in this respect by the rough-and-tumble work of investigating the physical world, is apt to regard the more tender organ of the mathematician with that feeling of impatience, not unmingled with contempt, which the man of the world manifests for what he considers to be over-scrupulosity and unpracticality.

It is true that we cannot conceive how such a science as mathematics could have come into existence apart from physical experience. But it is also true that physical precepts, as given directly in unanalysed experience, are wholly unfitted to form the basis of an exact science. Moreover, physical intuition fails altogether to afford any trustworthy guidance in connection with the concept of the infinite, which is in some form indispensable in the formation of a coherent system of mathematical analysis. The hasty and uncritical extension to the region of the infinite, of results which are true and often obvious in the region of the finite, has been a fruitful source of error in the past, and remains as a pitfall for the unwary student in the present.

Digitized by Google

The school of thought which has most emphasised the purely logical aspect of mathematics is that which is represented in this country by Mr. Bertrand Russell and Dr. Whitehead, and which has distinguished adherents both in Europe and in America. The ideal of this school is a presentation of the whole of mathematics as a deductive scheme in which are employed a certain limited number of indefinables and unprovable axioms, by means of a procedure in which all possibility of the illicit intrusion of extraneous elements into the deduction is excluded by the employment of a symbolism in which each symbol expresses a certain logical relation.

The actual evolution of mathematical theories proceeds by a process of induction strictly analogous to the method of induction employed in building up the physical sciences; observation, comparison, classification, trial and generalisation are essential in both cases. Not only are special results, obtained independently of one another, frequently seen to be really included in some generalisation, but branches of the subject which have been developed quite independently of one another are sometimes found to have connections which enable them to be synthesised in one single body of doctrine. The essential nature of mathematical thought manifests itself in the discernment of fundamental identity in the mathematical aspects of what are superficially very different domains. The mathematical physicist is familiar with the fact that a single mathematical theory is often capable of interpretation in relation to a variety of physical phenomena. In some instances a mathematical formulation, as in some fashion representing observed facts, has survived the physical theory it was originally devised to represent. In the case of electromagnetic and optical theory, there appears to be reason for trusting the equations, even when the proper physical interpretation of some of the vectors appearing in them is a matter of uncertainty and gives rise to much difference of opinion; another instance of the fundamental nature of mathematical form.

One of the most general mathematical conceptions is that of functional relationship, or "functionality." Starting originally from simple cases such as a function represented by a power of a variable, this conception has, under the pressure of the needs of expanding mathematical theories, gradually attained the completeness of generality which it possesses at the present time. The opinion appears to be gaining ground that this very general conception of functionality, born on mathematical ground, is destined to supersede the narrower notion of causation, traditional in connection with the natural sciences.

In conclusion, I propose to say a few words about some matters connected with the teaching of the more elementary parts of mathematics. Of late years a new spirit has come over the mathematical teaching in many of our institutions, due in no small measure to the reforming zeal of Prof. J. Perry. The changes that have been made followed a recognition of the fact that the abstract mode of treatment of the subject that had been traditional was not only wholly unsuitable as a training for physicists and engineers, but was also to a large extent a failure in relation to general education, because it neglected to bring out clearly the bearing of the subject on the concrete side of things. With the general principle that a much less abstract mode of treatment than was formerly customary is desirable for a variety of reasons, I am in complete accord. It is a sound educational principle that instruction should begin with the concrete side, and should only gradually introduce the more general and abstract aspects of the subject; an abstract treatment on a purely logical basis being reserved only for that highest and latest stage which will be reached only by a small minority of students. At the same time I think there are some serious dangers connected with the movement towards making the teaching of mathematics more practical than formerly, and I do not think that, in making the recent changes in the modes of teaching, these dangers have always been successfully avoided.

Geometry and mechanics are both subjects with two sides: on the one side, the observational, they are physical sciences; on the other side, the abstract and deductive, they are branches of pure mathematics. The older traditional treatment of these subjects has been of a mixed character, in which deduction and induction occurred side by side throughout, but far too much stress was laid upon the deductive side, especially in the earlier stages of instruction. It is the proportion of the two elements in the mixture that has been altered by the changed methods of instruction of the newer school of teachers. In the earliest teaching of the subjects they should, I believe, be treated wholly as observational studies. At a later stage a mixed treatment must be employed, observation and deduction going hand in hand, more stress being, however, laid on the observational side than was formerly customary. This mixed treatment leaves much opening for variety of method; its character must depend to a large extent on the age and general mental development of the pupils; it should allow free scope for the individual methods of various teachers as suggested to those teachers by experience. Attempts to fix too rigidly any particular order of treatment of these subjects are much to be deprecated, and, unfortunately, such attempts are now being made. Of the many evils which our examination system has inflicted upon us, the central one has consisted in forcing our school and university teaching into moulds determined not by the true interests of education, but by the mechanical exigencies of the examination syllabus. The examiner has thus exercised a potent influence in discouraging initiative and individuality of method on the part of the teacher; he has robbed the teacher of that freedom which is essential for any high degree of efficiency.

The great and increasing importance of a knowledge of the differential and integral calculus for students of engineering and other branches of physical science has led to the publication during the last few years of a considerable number of text-books on this subject intended for the use of such students. Some of these text-books are excellent, and their authors, by a skilful insistence on the principles of the subject, have done their utmost to guard against the very real dangers which attend attempts to adapt such a subject to the practical needs of engineers and others. It is quite true that a great mass of detail which has gradually come to form part—often much too large a part—of the material of the student of mathematics, may with great advantage be ignored by those whose main study is to be engineering science or physics. Yet it cannot be too strongly insisted on that a firm grasp of the principles, as distinct from the mere processes of calculation, is essential if mathematics is to be a tool really useful to the engineer and the physicist. There is a danger, which experience has shown to be only too real, that such students may learn to regard mathematics as consisting merely of formulæ and of rules which provide the means of performing the numerical computations necessary for solving certain categories of problems which occur in the practical sciences. Apart from the deplorable effect, on the educational side, of degrading mathematics to this level, the practical effect of reducing it to a number of rule-of-thumb processes can only be to make those who learn it in so unintelligent a manner incapable of applying mathematical methods to any practical problem in which the data differ even slightly from those in the model problems which they have studied. Only a firm grasp of the principles will give the necessary freedom in handling the methods of mathematics required for the various practical problems in the solution of which they are essential.

INTERNATIONAL TELEGRAPHIC COMPETITION IN 1911.

In our issue of July 1st we stated that the Italian Minister of Posts and Telegraphs had issued invitations to the Government Telegraph Administrations and the telegraph companies adhering to the International Telegraph Convention, the Imperial Chinese Telegraph Department, and the other principal private telegraph companies to participate in a competition in the transmission and reception of messages with Morse, Hughes and Baudot apparatus at the Turin International Exhibition next year. The following is an abstract of the regulations, which have already been approved by the Telegraph Administrations of Austria, Spain, France and Turkey:—

The tests will commence on August 22nd, and will be open to male or female members of the staffs of telegraph administrations and army or navy telegraphists. Applications to be sent by June 15th next to the Secretariat General, Bureau du Concours International de Telegraphie, Rome. The tests will include 20 minutes' transmission and 30 minutes' reception of messages by the Morse apparatus, the receiving being done with either the sounder or the writing instrument; and one hour of transimisson by Hughes apparatus, mechanical or electrical, and with either E or W key; and one hour of transmission by Baudot quadruple apparatus. The text will be in languages suitable to the operators, will be printed on sheets containing 50 words each, and will consist of words, groups of letters and figures. The text will be different for each system, but the same for competitors in the same system. A special test for reception by sounder and the writing of the text by a writing machine (the writing machine being provided by the competitor) will also be held, if not less than 10 competitors belonging to three different administrations apply by June 15, 1911. The transmission will be effected in accordance with the International Telegraph Regulations. There will be a championship cup, which will remain the property of the successful competitor, and which will be competed for by competitors who gain a prize in each of the three systems (Morse, Hughes and Baudot). There will also be an international representation prize cup to be competed for by groups of three competitors who all represent one State and have between them won prizes in all the three sections. There will also be individual prizes, 10 for the Morse, eight for the Hughes and eight for the Baudot tests.

Foreign competitors must present themselves at the Direction Supérieure des Postes et des Télégraphes de Turin two days before the tests commence.

THE ENGINEERING AND MACHINERY EXHIBITION AT OLYMPIA.

The third general engineering and machinery exhibition, which is being held this year under the more imposing title of the Naval, Mercantile Marine and General Engineering and Machinery Exhibition, was opened at Olympia yesterday by the Marquis of Graham. This exhibition has been organised by Mr. F. W. Bridges, assisted by a strong advisory committee under the presidency of Sir David Gill, K.C.B., F.R.S. As seems to be usual on these occasions, very few purely electrical firms are exhibiting, but the opportunity has nevertheless been taken to employ electricity for the general lighting of the building and for the driving of most of the machinery on the stands. We shall hope in due course to give a detailed account of some of the more interesting exhibits, and this week shall, therefore, confine ourselves to merely describing some of the things which ought to be seen by visitors to Olympia.

We may first mention that Messrs. Babcock & Wilcox on their stand have a number of interesting models. These models include one of a sea-going torpedo boat destroyer, which has been fitted with White-Foster water-tube boilers, for which Messrs. Babcock & Wilcox are the sole licensees. A model of a marine type water-tube boiler, as installed in various navies and in the mercantile marine, is also to be seen. Messrs. Babcock & Wilcox have supplied nearly 2,000,000 H.P. of these boilers. A standard land type of water-tube boiler, which is suitable for use in all industries, and of which 7,000,000 H.P. have been supplied, is also to be found on this stand. This boiler is fitted with one of Babcock & Wilcox patent steam superheaters. Other models are those of a patent chain grate stoker, a Lassen & Hjort water purifier, a collection of wrought steel steam piping with wrought steel flanges, and samples of headers used in the construction of Babcock boilers with pieces of tubes expanded therein. There is also a collection of turbine tube cleaners for removing scale from the inside of boiler economisers and other tubes.

An interesting series of ship models is to be found on the stand of Messrs. Cammell, Laird & Co., of Birkenhead. These include the "Leviathan," one of the largest dredgers in the world, models of the two latest additions to the fleet of the London & South Western Railway Co., and other similar passenger steamers which have been supplied to the Great Western Railway Co.

Messrs. Pickerings (Ltd.), of Stockton-on-Tees, are showing several designs of lifting and hauling appliances, amongst which is their electric friction hoist. This is driven by a motor through cut spur wheel and raw hide pinions, the special feature being the arrangement of eccentric for throwing the friction surfaces together. They are also exhibiting one of their self-sustaining dinner lifts, and a travelling trolley with two hooks, also of the sustaining type. It may be mentioned that this firm make a special feature of push button electric lifts for all kinds of services.

Messrs. Geo. Kent (Ltd.) are showing a number of apparatus illustrative of their specialities. Among these may be mentioned the Venturi station meter for gas works and the Venturi air meter for use where compressed air is employed. We understand that this type of meter is being used in connection with the supply from the Victoria Falls and Transvaal power scheme to the mines. A number of Kent's well-known Venturi water meters are also being shown. This firm is also exhibiting for the first time their "Uniform" hot water heater. This is guaranteed to be suitable for any temperature of water, and is, it is claimed, a perfectly satisfactory, reliable instrument at low pressures.

The Worthington Pump Co. are showing a large number of their well-known pumps. Among the working exhibits is a 1,600 sq. ft. Worthington condenser, which operates in connection with electrically-driven Worthington centrifugal circulating and hot well pumps with Worthington rotary air-pump. There is also a 4 in. three-stage centrifugal boiler feed pump driven by a 50 H.P. turbine. On this stand are also to be found a number of Worthington low-lift centrifugal pumps with couplings, marine low-lift centrifugal pumps with belt drive, and a 3 in. steam-driven centrifugal marine pump. A centrifugal house tank pump of the single-stage type and motor driven may also be seen.

Messrs. J. Marse & Co. are showing a Piat hydro-electric riveting machine of a portable type. This machine will close 340 $\frac{1}{8}$ in. diameter rivets per hour, the capacity of the motor being $2\frac{1}{2}$ H.P. The total weight of the machine is 14 cwt. It is claimed for this arrangement that it is easy to transport, no large plant is required, and it is always ready for use, while, unlike purely hydraulic apparatus, it can be worked, however low the temperature.

The Lea Recorder Co. are showing a new instrument for integrating as well as indicating and recording the flow of water over V notches and weirs. Mr. Lea's apparatus has been described from time to time in The Electrician, but our readers will doubtless take the opportunity of inspecting the latest patents shown at Olympia.

The Adams, Watkin Co. are showing the Adams-Watkins switch in a specially arranged exhibit which has been fitted up to demonstrate the facilities afforded by the switch for reducing the candle-power of electric lamps. Instruments are fitted up which show how the current in the circuit is cut down when the light is lowered. This switch has recently been described in detail in The Electrician.

Messrs. Stockall, Marples & Co. are exhibiting time recorders, electric clocks and watchmen's tell-tales.

Messrs. Clarke, Chapman & Co. have taken stand No. 166. The firm are showing a number of photographs of their various productions, including all classes of ship's deck machinery, windlasses, winches, capstans, &c., driven both by steam and electricity; electric machinery of all descriptions, including hauling gears, search-light projectors, &c.; water-tube boilers (Woodeson's patents), direct-acting steam feed pumps and various models, including one of the Clarke-Chapman water-tube boiler (Woodseon's patent).

We may also mention the exhibits of the Standard Engineering Co., who are showing a variable-speed single-phase motor, as well as the Stanlock multiple unit system, which is used in connection with the heating and ventilating of engineering workshops.

Other exhibitors are Messrs. Kelvin & James White and the Witton-Kramer Tool & Hoist Co. We shall hope to describe these exhibits in greater detail in another issue, but the names of these firms are sufficient indication of the apparatus they are showing.

LEGAL INTELLIGENCE.

British Westinghouse Electric & Mfg. Co. v. Redings Arc Lamp Co.

This action came before the Vacation Court on Wednesday upon a motion for an interlocutory injunction to restrain an alleged infringement of patent. Counsel stated that an injunction had been granted ex parte over that day and defendant now agreed to treat the motion as the trial of the action, submit to a perpetual injunction, an inquiry as to damages and delivery up of the infringing articles and to pay costs. Order accordingly.

Mining Regulations.

At Linlithgow on Tuesday Sheriff MacLeod gave judgment in a case of much interest to mine owners and managers. John Leckie, mine manager, Blackridge, was recently charged with having, on March 4 last, in No. 3 Blackrigg Colliery, Torphchen (occupied by the United Collieries, Ltd.), failed to see that a competent person was on duty at the colliery when the electrical apparatus or machinery installed there for driving pumps was in use.

The prosecution arose out of a fatal accident to a pump attendant in the pit by his coming in contact with a faulty joint of an electric cable. The Home Office desired a decision as to what was a competent person within the meaning of their special rules for the working of electrical plant in mines.

His Lordship said the question was whether what Mr. Leckie did was sufficient. He did not know what Mr. Leckie did. Therefore, he could not say whether it was sufficient or not, and he found the charge not proven. He had taken the liberty of making a suggestion to the Home Office. It seemed to him that H.M. Inspector of Mines ought always to find out on going to a mine what the manager had done, and he had suggested a very simple expedient by means of which the inspector should always be able to find out what he had done.

The Home Office will appeal from the decision.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the vacant position of assistant lecturer in the physics department of the Technical College, Sunderland. Commencing salary £150 per annum. Particulars from the assistant clerk to the Education committee (Mr. Herbert Reed), 15, John-street, Sunderland. Applications by Sept. 10. See also an advertisement.

First-class managers, experienced in the design, costing, testing and laying of all classes of insulated cables are required for new cable factories (two on the Continent and one in the East); those with knowledge of French and German preferred. Applications to the Eastern Trading Co., 4, Coleman-street, London, E.C. See an advertisement.

Digitized by Google

A first-class foreman is wanted for the rubber department of an Italian cable manufacturer. See advertisement.

An outdoor representative is required for a London Electric Supply Co. See advertisement.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

An assistant designer is wanted for a.-c. motors, familiar with calculation, construction and testing of all sizes from ¼ B.H.P. to 50 B.H.P.

Mr. Hy. Wren, M.A., Ph.D., D.Sc., has been appointed professor of pure and applied chemistry at the Municipal Technical Institute, Belfast.

Mr. Howard, of Taunton, has been appointed borough electrical engineer by Taunton Corporation.

EDUCATIONAL NOTICES.

King's College (University of London).—In the Faculty of Engineering complete courses of study, extending over three or four years, are arranged in civil, mechanical and electrical engineering for the engineering degrees of the University of London and for the diploma and certificate of the College. There will also be special courses of advanced lectures on "Internal Combustion Engines" and "The Theory and Practice of Construction." The entrance day for new students is Tuesday, Oct. 4.

University of London, Goldsmiths' College.—The new session commences on Monday, Sept. 26, and the enrolment of students commences on 19th inst. Complete courses of instruction are provided in mechanical, electrical and constructional engineering, telephony, fitting and machine pattern making and smithing, land surveying, &c. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education and City and Guilds of London Institute and for the National and Whitworth scholarships. There are reduced fees to course students if paid by Sept. 23. Particulars of fees, &c., from the Warden, Goldsmiths' College, New Cross, S.E.

University of Bristol.—At this university complete courses of instruction in electrical, mechanical and civil engineering are given, and also instruction in the evening classes. The 1910-11 session in the faculties of arts, science and medicine will commence on Oct. 3, and in the faculty of engineering on Sept. 13. Particulars and prospectuses from the registrar, Mr. James Rafter.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

University College of North Wales (Bangor).—In October a systematic course of instruction in electrical measurements and practical electricity for students proposing to enter the profession of electrical engineering will be commenced. The physical laboratory is well equipped for experimental and research work. The course extends over two sessions. Prospectus and further information may be obtained from the secretary and registrar, Mr. J. E. Lloyd, M.A.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

Glasgow and West of Scotland Technical College.—The day classes begin on Tuesday, Sept. 27, and the evening classes on Thursday, Sept. 22. The diploma of the College is granted in civil, mechanical and electrical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study for the diploma usually extend over three sessions, and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow after attendance for at least one session upon prescribed University classes. Preliminary examinations begin on Sept. 19. There are new and well-equipped laboratories in the departments of physics, chemistry, mechanics, motive power and electrical engineering, &c., and facilities are afforded for research. Copies of calendar (price 1s. 4d.) and prospectus (gratis) can be obtained from the Secretary.

South-Western Polytechnic Institute (London, S.W.).—At this Institute a complete three years' course in electrical engineering is held during the day, and a four years' course in the evening. Courses of lectures and practical work are given in a number of subjects, including elementary, intermediate and advanced electrical engineering, electrical design, instruments and lamps, alternating and polyphase currents, wiring and fitting, and the calculus for engineers. Particulars from the Secretary, Manresa-road, Chelsea, S.W.

BRITISH NOTES.

Bispham.—The Council have decided to apply for sanction to a loan of £9,855 for electricity supply and dust destructor works. The consulting engineer is Mr. J. W. Speight, and it is estimated that the cost of site for a generating station (which has been conditionally purchased) will be £2,105, while the generating plant, mains, &c., will cost £7,200.

Bradford.—At a meeting of the Tramways committee on Monday a sub-committee was formed to carry into effect the provisions of this year's Corporation Act, authorising the construction of railless tramways, and it is anticipated that a line will be in operation in the near future.

Braunton.—The Parish Council have received a favourable report from Mr. Jenkins on the electricity supply scheme proposed by Messrs. Crompton & Co., and it is probable that a contract will be entered into for public lighting in the event of the scheme being carried out. The majority of the inhabitants favour electric lighting, and an effort will now be made to form a local company.

Brighton.—Yesterday (Thursday) the Council had under consideration a report from the engineer and manager of the electricity department (Mr. John Christie) in regard to the condition of the pipes of the condenser circulating system at the Southwick electricity works.

In his report Mr. Christie states that at the last meeting of the Lighting committee he verbally reported that they were experiencing trouble due to mussel spawn and other marine growths having got through the strainer and attached to the inner surfaces of the pipes of their condenser circulating system. These growths had increased in size and multiplied in a most alarming manner. Further investigation showed that the trouble was more serious than at first anticipated. There was a 5 ft. suction pipe from the harbour, which, some 10 ft. inside the face of the quay, branched off into two 30 in. pipes. A diver went up the 5 ft. pipe as far as the branch, and reported that beyond it there were clusters of large mussels and other marine growth, some 7 in. thick, all round the inner surface of the pipes. That reduced the effective bore of the 30 in. pipe to 16 in., greatly restricting the flow of water to the condensers, and putting an overload on the pumps and motors which they were never designed to carry, in order to circulate sufficient volume of cold sea water to effectively condense the steam and maintain the high vacuum, so necessary for the efficient operation of the turbines.

Mr. A. Wright had unfortunately been detained in South Africa by illness, and he had been unable to discuss the matter with him. He had, however, gone fully into the matter with his deputy, and he had consulted several expert marine biologists, and a few station engineers who had to work their plant under somewhat similar conditions. They all agreed that there was no cure for the trouble except scraping the growth off the pipes by some mechanical means and removing the debris. It was quite impossible to do that in their case, and the only alternative was to provide a new system of pipes laid above the floor, with suitable manholes to give access to them for the periodical scraping and removal of any growth that might accumulate. Their new turbine, which they were arranging to erect in a few months time, was originally intended to be coupled up to the existing circulating system. In view, however, of the unfortunate development, it would be best to connect it up to an entirely new system of piping. With that end in view he had had a new scheme of pipe arrangement got out, embodying a pipe line for the new turbine and four new pipe lines which could be worked in in the same way to each of the existing turbines in turn, each set being distinct from the others and entirely disconnected from one common pipe system as at present. He had discussed the question with Messrs. Richardsons, Westgarth & Co. (the makers of the turbine) and they approved the new arrangement. They quoted £870 for supplying the necessary pipes, valves, &c., to connect up the condenser of the new set with the harbour. That would work in with the complete scheme, and they would have to carry out the excavation for and laying of these pipes themselves by direct labour, and he asked the Lighting committee to approve of the work being put in hand at once, and for authority to invite prices from some of the leading pipe makers for the remainder of the pipes necessary to run a new system to each of the first four turbines. The cost will be approximately £1,800, exclusive of the cost of excavation and erection. The cost of the piping

Digitized by Google

for the new turbine should (Mr. Christie considers) form a capital charge, but the cost of supplying similar arrangements for the first four turbines would have to be met out of reserve. As the summer is now gone, and the mussel growth will not seriously increase before next spring, and with the temperature of the sea water gradually falling, and consequently the amount of water necessary for cooling the steam getting proportionately less, Mr. Christie hopes that, with the fifth turbine coupled up to a new system of pipes, as suggested, they will be able to get through this winter's load without mishap.

The Lighting committee reported that they considered that the only means of dealing with the matter was to carry out the suggestions set out in Mr. Christie's report, and they recommended that tenders for carrying out the necessary work be called for.

Chelmsford.—The Guardians propose to provide electric power plant for the workhouse laundry at a cost of £560.

Church Lighting.—The Causewayend U.F. Church, Aberdeen, has recently been re-decorated and fitted for electric lighting. The wiring work was carried out by Mr. J. Jackson and the fittings and pendants were supplied by Messrs. Benson & Co. The entrance hall is lighted by two 50 c.p. osram lamps, two side entrances and staircases have each a single pendant with 50 c.p. lamps. Along each aisle are four solid bowl pendants, each with three 50 c.p. lamps on two switches. The back gallery is lighted by a similar bowl pendant, and arranged under the galleries are 13 single 50 c.p. pendants.

Cobham.—The Woking Electric Light Co. propose to commence laying cables in this district in about five weeks. The Parish Council are to invite tenders from the electric light and gas companies for street lighting. At present oil lamps are used.

Electric Pumping in Emergency Work.—Recently a serious fire occurred at the Stoney Heap pit of the Consett Iron Co., owing to the ignition of some oil or waste used in connection with an oil engine driving a pump. After the fire was extinguished there was danger of the workings being flooded out unless within a week a replace pump equipment was in commission. The Cleveland & Durham County Electric Power Co. came to the rescue by running a cable from their main transmission system, about ½ mile away, to the pit head, where a step-down transformer was installed, from which about 350 yds. of 440-volt cable was run to a 60 H.P. motor, which, together with the necessary pump, had been hurriedly secured. The work was completed in good time to allow of pumping operations being resumed before the water had encroached dangerously. This instance affords an excellent example of the advantage of the existence of a network of electric power mains throughout the colliery districts of Durham.

Exhibition Award.—We are pleased to announce that the Japan-British Exhibition authorities have awarded the Grand Prize (the highest possible award) to Mr. Louis Brennan for his gyroscopic mono-rail invention.

Grassington.—A meeting of ratepayers called by the Parish Council was held on Tuesday, when it was decided to approve the electric lighting scheme put forward by Grassington Electric Supply Co. At present £30 per annum is paid for lighting, but the company will give a much better light for £20 per annum.

Greystones (co. Wicklow).—At a recent meeting of Rathdown (No. 2) Rural Council a discussion took place on the proposal to adopt public electric lighting.

The L.G. Board had written stating that they were not aware of any authority empowering the Council to borrow if they did not themselves intend to apply to the Board of Trade for a provisional order, or licence, authorising them to supply electricity.

It was also stated that counsel's opinion was that the Greystones Electric Light Co. could not enter into a contract for public lighting without first obtaining a provisional order. Until this was done the Council had no power to come to an agreement with the company.

Mr. Hewson said he knew, as a matter of fact, that other urban districts had done their lighting without a provisional order being obtained. It was done at Ballinrobe and other places. It was the policy of the L.G. Board to play into the hands of the Board of Trade, and to put the ratepayers to expense. They should imitate the West of Ireland, and carry out their lighting without bothering themselves about the Board of Trade. Mr. Hewson undertook to make inquiries, and report to the next meeting.

[We believe that in rural districts powers for public lighting (by electricity or gas) are obtainable for any parish or part of a parish in a district under the Lighting and Watching Act, 1833, and provided the act is adopted in the regular way for the district (or any parish in it) the Council can then enter into a contract with a company for the supply of electricity and the erection and maintenance of the lamps. It is not necessary that the Council should borrow for this purpose. In fact, it is not a charge which should fall upon capital.—ED.]

Halifax.—A sub-committee of the electricity committee recommend the purchase and erection of additional generating plant at the electricity works at a cost of £10,000.

The additional plant is required in order to meet the increased demand for electrical energy, especially for power. In the proposed Parliamentary bill further borrowing powers will be sought.

Haslingden.—The Board of Trade has sanctioned the arrangement whereby Accrington Corporation is to supply electricity to Haslingden, and the question of the revocation of the Haslingden electric lighting order has been deferred for a year from Sept. 30.

Inquest.—An inquest was held at Pencoed on Tuesday into the death of a collier named Jones, who was killed at South Rhondda Colliery on 19th ult.

EDWARD JORDAN said he and deceased were working on the night shift putting up iron girders. Deceased picked up a few yards of old loose signal wire which was lying on the side of the roadway to hand to witness. He had no sooner done so than he shouted and fell down, apparently dead. Witness tried to take the wire from him, but was rendered unconscious for a few seconds by a shock.

JOHN MATTHEWS said he heard a scream and saw a flash of light. On running to the spot he saw deceased lying on the ground with the wire in his hand. The wire extended across the roadway to the electric cable. He caught hold of the cable, using india-rubber gloves, and cut it. He unsuccessfully tried artificial respiration. He examined the cable and found that the signal wire, which Jones had picked up, was hitched into the cable near the joint, and some of the insulating tape around the joint had got loose. Witness believed the tape had been pulled loose by the piece of wire catching into it—that a sharp end of the wire had cut through the tape to the core of the cable.

WILLIAM DAVID, mechanic, said the electrical apparatus was under his supervision.

Mr. R. NELSON (H.M. electrical inspector of mines): Were you present on Monday when I opened four joints in the cable and found no empire tape?—Yes; we had an electrician. We thought he was not using sufficient empire tape. I spoke to him about it, but he said he was using it.

Is that electrician with you still?—No, he has left. We disagreed about something else, and he went.

Mr. W. WILLIAMS, manager, said he had notices posted up in the colliery about the electrical installation. At the spot where the accident occurred the cable was carrying continuous current at 300 to 400 volts.

Mr. R. NELSON said he examined the cable generally. He concluded from the evidence that the shock was conveyed in some way from the piece of disused signal wire. Whenever repairs were being carried on, or girders erected, electrical cables should certainly be protected. Disused wires should always be removed, and not be left on the roadway where there were electrical cables.

A verdict of accidental death was returned., and the jury added a rider that death was due to electric shock, but that there was not sufficient evidence to show whether the cable was defective at the point where the accident occurred. They were of opinion that the recommendations of Mr. Nelson should be strictly carried out at all collieries.

Llanelly.—The Llanelly & District Electric Lighting & Traction Co., which recently made an issue of capital, has acquired a site for a generating station. A contract has been made with Messrs. Balfour, Beatty & Co. for the erection and equipment of the station, which will have an initial capacity of 1,000 kw. A portion of the tramway system has been re-constructed for electric traction, and the remainder will be re-constructed next year. The Council have entered into a 10 years' contract with the company for street lighting, which will be effected by 40 arc lamps and over 500 incandescents.

Municipal Wiring.—We have received from the hon. secretary of the Incorporated Municipal Electrical Association (Mr. H. Faraday Proctor), of Bristol a list of the municipal electricity undertakers which have replied to his circular letter of July 9, in connection with the promotion of a bill for further powers, including authority for municipal electricity departments to wire consumers' premises, let motors on hire, &c.

The following 36 towns will give financial support: Barnes, Barrow, Bolton, Blackpool, Bradford, Cardiff, Coventry, Devonport, Dewsbury, Eastbourne, Eccles, Govan, Gillingham, Hastings, Ilkeston, Ilford, Londonderry, Lincoln, Maidstone, Middlesbrough, Peterborough, Portsmouth, Rochdale, Sheffield, St. Marylebone, St. Helens, Taunton, Walsall, West Ham, Wimbledon, Wigan, Edinburgh, Glasgow, Bristol, Doncaster.

The following 12 towns have decided to give the bill their moral support: Birkenhead, Bury, Broughty Ferry, Colne, Canterbury, Dartford, Exeter, Fulham, Falkirk, Hackney, Loughborough, Southend-on-Sea, West Bromwich, Warrington and Halifax.

Brighton, Carlisle, Darlington, Keighley and Swindon are in favour of the proposal, but the following will take no action: Aberdeen, Epsom, Farnworth, Grimsby, Hammersmith, Ipswich, Liverpool, Salford, Southwark, Tunbridge Wells, Batley and Sutton Coldfield. Derby Electricity committee will consider the matter again. Hull has replied "Yes" as regards stand-by by unauthorised undertakers, but not wiring; and Mansfield already possess the powers.

Newcastle-on-Tyne.—Deputations from the Newburn and Blaydon Councils have waited upon the sub-committee of the Tramways committee dealing with the extension of the municipal tramways by railless trolley routes or otherwise, in order to urge the necessity of improved transit facilities in Newburn and Blaydon respectively. The sub-committee is favourable to the principle of extension, but a further meeting will be held between the parties.

Digitized by Google

Nottingham.—The Corporation have commenced the construction of the Carlton-road tramway route. The line, about a mile in length, will be double throughout, and the estimated cost is £13,000.

Obituary.—We regret to record the death of Col. Sir Charles Euan-Smith, K.C.B., C.S.I., which occurred in London on Tuesday. Deceased, who was 68 years of age, was associated with several electric tramway and lighting undertakings, and was chairman of the Cape & Lisbon Electric Tramways Companies, a director of the Chilian Electric Tramway & Light, Marconi's Wireless Telegraph and the Marconi International Marine Intercommunication Companies.

We also regret to record the death of Mr. William Anderson, manager, and since 1896 managing director of the Dublin United Tramways. Mr. Anderson was also a director of the Cork Electric Tramways & Lighting Co.

The death is also announced of Herr Isidor Loewe, of Berlin. Deceased was associated with Ludwig Loewe & Co. and other German companies. In 1892 he founded the Union Electrical Co. (Berlin) in connection with the Thomson-Houston Electrical Co. of Boston for the construction of electric railways on the Thomson-Houston system. Herr Loewe was also connected with the management of a number of important financial and industrial enterprises.

The death took place in London on Aug. 24 of Arthur Willoughby Foord, Director of Indian Government Telegraphs. Deceased was 50 years of age.

Overcrowding on Tramcars.—At a recent meeting of the Plymouth Tramways committee a letter was received from the Board of Trade asking for an explanation of overcrowding of tramcars on recent occasions.

The tramcars are allowed to carry seven excess passengers on Saturdays from noon, on Sundays and holidays, and on other days when the weather is inclement.

The committee received a report from the tramways manager (Mr. Everson), in which it was stated that the utmost pains had been taken to find out where and when 10 and 15 passengers were seen standing in a tramcar at any one time, and he had been unable to find a single occasion, except occasionally when three or four people were on top of a car when a downpour of rain came on. These people rushed from the top and took shelter from the heavy rain on the platform and inside the car.

After reading the reports on the matter, the committee decided to reply that strict instructions had been issued to the inspectors and conductors and that those instructions had been strictly adhered to, except very occasionally.

A report has been received from the borough surveyor (Mr. Jas. Paton), the electrical engineer (Mr. E. G. Okell), and the tramways manager (Mr. Everson) on the relative cost of establishing a service of cars on the railless trolley and the ordinary tramway systems to Laira, and also on the cost of extending the tramways to the borough boundary at Hartley. The committee are to inspect the routes on the 13th inst., and will then consider the reports.

Presentation.—Chatham Dockyard electrical engineers' staff have presented a travelling bag, a case of pipes and a safety razor to Mr. W. J. Rhodes, who has been appointed inspector of electrical fitters at the Cape of Good Hope Dockyard.

Railway Employees' Wages and Hours of Labour.—The Railway Department of the Board of Trade have issued as a blue book a statement of settlements regarding questions as to rates of wages and hours of labour of railway employés that have been effected under the conciliation scheme of November, 1907, and of settlements on certain railways which remained outside the scheme.

Particulars are voluntarily supplied of settlements arrived at upon four railways not under the general scheme, viz., the City & South London, Underground Electric Railways of London, Metropolitan District and North-Eastern Railways. As to the methods of arriving at decisions under the conciliation scheme for the different railways, the return shows that settlements were made by sectional conciliation boards in 23 instances, while the conciliation boards effected settlements in three or four cases. Intervention by the central conciliation board proves to have been fairly common, while many settlements were effected "through usual channels," and a few by arbitration.

Ramsbottom.—The official inauguration of electricity supply for private lighting and power took place on Saturday last.

Seaforth (Ont.).—The ratepayers recently voted in favour of the acceptance of the offer of the Hydro-Electric Commission to supply electricity in bulk, and £5,000 has been voted for the equipment of a transformer sub-station and the laying of a distribution network.

Sewage Pumping.—An L.G. Board inquiry has been held into an application of Doncaster Rural Council for sanction to a scheme of main sewerage and sewage disposal for Adwick-le-Street and property near the station.

It is proposed to convey the sewage of a portion of the district to an underground pumping station where storage tanks will be provided, and the sewage pumped to the Woodlands sewage disposal works automatically by electric motors driving centrifugal pumps. The other portions will gravitate to the works. The population to be dealt with at the works will be about 12,000. The scheme has been designed by Messrs. D. Balfour & Son, of London and Newcastle-on-Tyne.

Strike.—On Aug. 25 a strike of pattern makers commenced at Preston, in consequence of their demand for an increase of their wages by 2s. per week not having been conceded. It is stated that the men's demand for an advance in wages was due to an abnormal demand for labour caused by the engagement by Messrs. Dick, Kerr & Co. of between 60 and 70 men to make steam turbine patterns.

Todmorden.—An unopposed inquiry was held into the Council's application for sanction to borrow £300 for the electric lighting of the town hall.

Village Lighting.—At Askrigg electricity has been adopted for street lighting, and the Wesleyan Church, the Queen's Arms Hotel and a number of private houses have been wired. Water power is used in generating current.

A Wireless News Service.—It is announced that the Marconi Wireless Telegraph Co. are about to establish a news service which promises to be of considerable interest. The results of recent arrangements for establishing communication between ships at sea and the authorities on shore have pointed to the feasibility of establishing a central office for the regular collection of news items from ships at sea and at the same time, of course, conveying news from shore to ship. The fact that a large and increasing number of the principal steamships are now equipped with Marconi apparatus gives the proposal a promising appearance. The new service will be established within the next few weeks.

Wireless Telegraphy in the Pacific.—In our last issue, under the heading of Wireless Telegraph Notes, we gave a long extract from a recent article in the "Canadian Electrical News." We have received the following communication on the subject of this note:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of Aug. 26, under "Wireless Telegraph Notes," you quote from an article in the "Canadian Electrical News" for August, which is full of discrepancies. For instance, the Canadian Government stations are not all equipped with Marconi apparatus. The original apparatus at Point Grey, Victoria, Cape Lazo, Pachena and Estevan was supplied by the International Telegraph Construction Co., of New Jersey, and consisted of the Shoemaker system. Each set was of 1 kw. capacity, and was covered by a guarantee, power being derived from a 3 H.P. Fairbanks-Morse gasoline engine. The masts, except at Point Grey, were 180 ft. high; at the latter place a standing Douglas fir, 300 ft. high, was used (after being stripped of its limbs, and an occupied bald eagle's nest, 7 ft. 6 in. in diameter).

On the appointment of a new superintendent, an ex-Marconi man—Marconi sets having double the power (2 kw.) were added to the Shoemaker sets at Cape Lazo, Victoria and Pachena. Supplement No. 10, dated July 15, 1910, of the Berne List of Radiotelegraph stations, shows Shoemaker sets to be in use at Victoria, Pachena and Estevan.

The article further states that "the tower at Triangle Island is 620 ft. high, and the 180 ft. mast makes this the highest station in the world." This is liable to lead to a misconception, because 620 ft. is undoubtedly a rough (and outside) estimate of the height of the top of the mast above sea level as the island is some 300 ft. high, and the cost of a 620 ft. tower would be altogether inconsistent with the vote for these stations.

I would add that the 1 kw. Shoemaker sets, at Pachena and Estevan, had a nightly range of communication extending from Sitka, Alaska to San Diego, Southern California, and could hear Honolulu.

The writer had local charge of the construction of five of the stations referred to.

A. H. MORSE,
Installer, United Wireless Telegraph Co. of New York.

[We cannot truthfully express regret for having quoted from our esteemed Canadian contemporary in view of the fact that it has given Mr. Morse an opportunity of correcting us by means of this very interesting letter. In the early days of the telegraph incidents of the kind set out in Mr. Morse's letter were frequent, and it is quite a reminder of old times to read of the expedients adopted by the installers of wireless telegraphy to overcome natural difficulties.—ED. *E.*]

A Reuter's message states that wireless communication was successfully established on Saturday last at Sheeps Head Bay aviation track, New York, from a moving aeroplane at a height of 500 ft.

In his report on the trade of Iquitos (Peru) for 1909, Consul Cazes says the wireless telegraphy system is still rendering good service, but communication with Lima and Europe is often interrupted beyond Puerto Bermudez, whence messages go by overhead cable.

The public journals relate that preparations are reaching completion for the crossing of the Atlantic Ocean by airship, driven by an American aviator, Mr. Wellman. This mighty effort is to be made towards the end of the current month of September, and it is arranged that the airship is to be provided with a Marconi wireless telegraph installation and night signalling apparatus to enable the six persons who are to be accommodated on board to communicate with creatures on terra firma. The reported success of the experiment at the aviation grounds at Sheeps Head Bay, New York, have satisfied the parties concerned of the practicability of the proposal.

"Robertson and Osram" Sports.—The fifth annual sports of the Robertson and Osram social and athletic club were held on Saturday last. 28 events were all keenly contested, and some fine sport, as well as amusement, was provided, the competition for supremacy between the employés at Robertson's Lamp Works, the Osram Lamp Works and the General Electric Co. being very keen, the number of handsome and useful prizes offered helping in this direction. Much credit is due to the committee and other officials for the excellence of the arrangements and management generally. After the competitions, Mrs. C. Wilson, wife of the genial president of the club, presented the prizes, after which dancing on the lawn was indulged in.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" states that Government has approved the statutes of the Compañia Hidro-Electrica de Tucuman.

About a year ago Santa Fé Municipality called for tenders for the electrification of its tramways. Several proposals were received, but all were rejected. Fresh tenders have just been received, and it is stated that none of them are as advantageous to the Corporation as those presented previously.

Australasia.—The "Australian Mining Standard" states that a deputation from Canterbury (N.Z.) recently waited upon the Prime Minister (Sir Joseph Ward) to urge that the Government should at once proceed with the Lake Coleridge hydro-electric power scheme for Christchurch, or that the Corporation should be allowed to do so.

Sir Joseph Ward, in reply, said the Government had rightly changed its policy in the bill that would be considered this session regarding water power, because they found that in some places large sums were being made out of options before any work was done. If that were permitted it would mean imposing upon the people very high charges for power. The Government could provide water power at a cheaper rate than any corporation, and they would not allow a superior body to have an opportunity of making an over-riding profit out of the business. Legislation on the subject would be put through this session. They would not, of course, spend the whole of the £500,000 in Canterbury. They had come to the conclusion that it was in the best interests of the State that the Government should control the whole of the powers for utilising water power from end to end of New Zealand.

Wellington (N.Z.) city electrical enigneer (Mr. Stuart Richardson) reports that the Parsons 1,500 kw. turbo-generator at the Mercer-street station has been running continuously and has given complete satisfaction since the beginning of this year. Mr. Richardson estimates that the machine will effect a saving of nearly £3,000 per annum in generating expenses. The coal consumption has been reduced by 1,600 tons in the half-year (equal 25 per cent.).

In the Tasmanian Legislative Assembly recently Mr. N. K. Ewing gave notice of a motion to advance to the municipalities of Huan, Lovett, Esperance and Kingborough moneys for the construction of an electric tramway from Hobart to Huonville, with branch into Kingston and connecting Huonville with Lovett and Geeveston, and for a line from Huonville up to the Huon river to tap the available Crown lands, and that the committee have power to enter into a contract to take electrical energy from the Complex Ores (Ltd.), or any other company acquiring their rights. The Complex Ores company are already negotiating with the municipalities for electric lighting.

Mr. A. H. Wood, electrical engineer, of Melbourne, has been engaged to report to the Yea & Mansfield (Victoria) Dairy Co. on a proposal to instal suction gas plant for operating electrical plant for lighting the company's works.

The Electric Supply Co. at Hamilton (Victoria) are duplicating their plant by putting down a 100 H.P. engine gas producer plant and dynamo.

Toora (Victoria) ratepayers are discussing a proposal to adopt electric lighting. Mr. A. H. Wood advises that the water power of the Agnes and Franklin rivers (both within three miles) could be utilised for generating current.

The Derwent Mfg. Co. is being formed to establish a hydro-electric plant on the Derwent river, near Hobart, Tasmania. Mr. H. J. Spencer (formerly electrical engineer to the Hobart Gas Co.) is connected with the scheme.

Chili.—The "Review of the River Plate" says the special committee appointed by the Chilian Government to report on the proposed electrification of several of the State lines and which will shortly have finished its work, are in favour of electrification.

Customs Decisions.—Electric tramrail filing machines driven by mechanical power can be imported into the Netherlands duty free.

Under the French Customs tariff porcelain insulators mounted on an iron or steel stand are dutiable under 347 *bis* and 558 *bis* if the parts are separable (*i.e.*, each part is dutiable separately), but if the parts are inseparable the whole pays duty at the highest rate applicable to any part.

By coils of insulated metallic wire, under the heading of "electric and electro-technical apparatus" in the French tariff, is to be understood all coils of wire having an insulation, such as wire surrounded by a covering of textile threads, by a sheath of ribbon, trimming or tissue, by an insulating coating with a base of indiarubber of gutta or any other material, except uncovered (bare) metallic wires set in a bobbin of porcelain, glass or pottery.

Electricity in Mining.—At the recent meeting of the Tasmanian Copper Co. it was announced that the electric power plant on order is on its way from England, and that the foundations, &c., for the first unit are ready.

Hydro-Electric Works in India.—"The Times" announces that an Indian company is in course of formation for the utilisation of water power (at Lanauli, in the Western Ghats) for generating electrical energy which would be transmitted to mills and factories at Bombay. The company is to have a capital of 170 lakhs of rupees (£1,133,220), 70 per cent. of which has been already subscribed. The scheme is to furnish 30,000 H.P., with a reserve of 10,000 H.P., and possibilities of expansion to 50,000 H.P. It is stated that this will be the biggest industrial enterprise inaugurated in India, except the Tata Ironworks.

Italy.—Application for a concession for the construction of an electric tramway from Bergamo to Albino has been provisionally approved by the Superior Council of Public Works.

Japan.—The report of Mr. E. F. Crowe, commercial attaché to H.M. Embassy (*Tok'o*), states that imports to Japan in 1909 included machinery to the value only of £2,072,500, compared with £3,498,600 in 1908 (a decrease of 40 per cent.).

This total included dynamos and motors £184,400 (£209,200) and other electrical machinery £121,800 (£170,600). Imports of telephones were £12,200 (£11,500), steam engines £72,000 (£180,300), gas, oil and hot air engines £39,100 (£98,700) and steam turbines £23,700 (£76,500). Exports of machinery were valued at £183,600 (£234,500). The total imports for the year included £8,802,416 (£11,004,630) from the United Kingdom and £16,275,603 (£16,849,278) from the British Empire, the largest increase being India £6,651,453 (£5,035,612), compared with the United States £5,516,907 (£7,925,398), Germany £4,105,540 (£4,724,266) and France £567,449 (£535,574). Imports included insulated electric wire £191,500 (compared with £190,600 and £251,400 in 1908 and 1907), electric cars £115,200 (£47,200 and £57,000).

One of the features of the year has been the activity with regard to water power schemes. There are already in many parts of the country small plants in operation supplying current to electric light and tramway companies. Of large hydro-electric undertakings, however, the only one which appears to be meeting with success is that of the Uji river, which is intended to supply Osaka. The other great consumer of power in Japan is the capital, Tokio, where there are five or more water power schemes under consideration. Two of these enterprises have been jointly undertaken by British and Japanese capitalists, but difficulties have arisen and it does not appear that either scheme is making progress.

Another noticeable feature of the year, especially of its closing months, has been the boom in electric tramway and gas undertakings, more particularly for the district round Osaka and Kobe and the south of Japan.

In November, 1909, the revised laws with regard to patents, trade marks, designs and utility models came into force. Already some satisfactory decisions have been given in trade marks cases which it would only have been possible to obtain with great difficulty under the old law.

Imports at *Yokohama* included submarine and underground cables £7,230 (compared with £22,518 and £99,180 in 1908 and 1907), other electric wires £90,421 (£108,681 and £64,800), electric machinery £126,045 (£181,551 and £134,370), steam turbines (German in 1909; British and U.S.A. in 1907-8) £6,464 (£22,571 and £21,690), steam engines (chiefly British) £16,090 (£59,608 and £52,100), steam boilers (chiefly British) £9,152 (£34,052 and £48,980), gas and petroleum engines (chiefly British) £20,564 (£49,818 and £33,160). Exports of machinery were valued at £98,560, against £124,072 and £141,350.

New Zealand Telegraphs.—The annual report of the N.Z. Post and Telegraph Department for 1909-10 states that the working expenditure of the telegraph department was £411,296. 17s. 2d. (against £394,649. 19s. 6d. in previous year), which exceeded the revenue by £16,786. 12s. 4d.

The bureau (telephone) messages have so greatly interfered with the ordinary telegraphic work that telegrams have barely held their own. Telegrams transmitted were 7,846,890 (increase 421,197, or 5·67 per cent.) and bureau (telephone) communications were 1,757,869 (against 1,423,093). On March 31 last there were 10,901 miles of telegraph line and 34,788 miles of telegraph wire. Submarine cables within the Dominion were 368 knots. There were 291 telegraph and 1580 telephone offices open. New Zealand's proportion of the deficit of £60,887. 9s. 10d. on the 1908-9 (seventh) year's working of the Pacific cable was £6,765. 5s. 6d. The estimated deficit for 1909-10 was £59,683, of which New Zealand's proportion is stated at £6,631.

Seventeen new telephone exchanges were opened during the year, the number of subscribers increased by 2,104, and the total number of connections by 2,848. There are now 153 exchanges. The total number of connections is 29,681, compared with 26,833 in 1909. On March 31, 1910, there were 1,270 miles of telephone line and 35,233 miles of wire. New switchboards were installed at Te Aroha, Paeroa, Te Kuiti, Greytown, Kimbolton, Manaia, Opunake, Pahiatua, Waipawa, Waitara, Woodville, Picton and Kumara, and two sections were added to the Auckland exchange switchboard, increasing the capacity to 3,599. The central battery equipment which was brought into operation at Invercargill and Timaru in June, 1909, has given entire satisfaction to subscribers, besides greatly facilitating switching operations. At Hastings the conversion to metallic circuit and the installation of the central battery system are well forward. The conversion of exchange subscriber's circuits from earth working to metallic was completed at Auckland, Wellington

Digitized by Google

Wanganui and Christchurch. Preliminary steps have been taken to establish the metallic circuit system at New Plymouth, Feilding, Hawera, Palmerston North, Napier, Gisborne and Masterton. In August, 1909, the work of laying conduits to provide for placing the telephone cables in Auckland City underground was commenced. Over five miles of lead cable, representing 1,615 miles 74 chains of twin wire, have been drawn into the underground ducts in Wellington City. Arrangements are being made to immediately erect two copper wires between Wellington and Auckland for telegraph purposes by a new route on the main trunk railway line, which is much shorter than the existing routes. These wires will also be used during certain hours for telephonic purposes between the two cities. Between Auckland and Whangarei (126 miles) a telephone circuit was superimposed on two telegraph wires with most satisfactory results. The two wires (Morse and telephone) between Nelson and Motueka have been utilised to form a trunk metallic circuit with the Morse superimposed over it. A similar circuit has been arranged between Nelson and Wakefield. Additional telephone circuits have been superimposed over existing metallic circuits between Ashurst and Palmerston North, Masterton and Greytown and Masterton and Eketahuna; and Morse circuits have been superimposed over metallic circuits between New Plymouth and Waitara, Manaia and Opunake and Wellington and Levin.

Norway.—It is intended to start electric smelting at Odda, in Hardanger, and an experimental electric steel furnace constructed by Eng. Ab. Hiorth at Jösingfjord has produced a few tons of steel. The electrical works were busy during 1909, and there has been a large export of telephones.

Among the new industrial projects in the Bergen district electric iron and steel smelting must be placed foremost. Two processes have been tried in Western Norway—viz., the Heroult method (tried at some smelting works at Trondhjem) and the Grönvall process, and a company is being formed for the erection of electric iron and steel smelting works near Odda, in Hardanger, the necessary electric power to be supplied by the Tysse Falls Co.

Work has been proceeding apace with the Bergen municipal hydro-electric works at Samnanger for supplying power for lighting and industrial purposes in the city, which is at present dependent on steam-driven plant. The work includes the blasting of a water tunnel over 2 miles long, and which, it is estimated, will take 2½ years to complete. The power station will contain machinery of 35,000 H.P. Current will be generated at 7,500 volts, then stepped up to 40,000 volts for transmission to Bergen. The six cables are to be about 22 miles long, and the works are to be completed by the first half of 1912, at an estimated cost of about £200,000.

A report is current that the erection of zinc smelting works is contemplated at or near Odda and also in Romsdalen.

Russian Trading Methods.—In a recent report on the trade of Kharkoff for 1909 Mr. Vice-Consul C. Blakey deals somewhat fully with Russian trade methods.

Mr. Blakey states that the usual advice of trade journals to British exporters to adapt themselves to local conditions by giving metric measures, prices in roubles, Russian, German or French correspondence and catalogues is of first importance in the smaller trades, and even the experienced commercial traveller is not in every case the all-powerful trade factor, and he can often be replaced by local commission agents. I do not mean (says Mr. Blakey) that commercial travellers are of little importance. Thus, for instance, machine tools are frequently sold by travellers, and I should say that in 1909 in the Alexandrovsk manufacturing district alone the increased demand for agricultural machinery will have brought orders to the amount of about £10,000 to the travelling representative of a Berlin tool merchant. In this case personal acquaintance and the patriotic views of the German manufacturers will have assisted to get the orders placed in Germany.

But the trade in which the United Kingdom should be particularly interested, and of which the British manufacturer might gain a larger share, the engineering business, is held by the Germans on a much sounder method, by thorough commercial and technical knowledge, by strenuous energy and financing. In face of a heavy tariff, and against the competition of excellently equipped Russian engineering works, they continue to supply machinery which, though of high quality, is probably neither cheaper nor better than the British. In electrical engineering, cranes, lifts, transporters, machine tools, pumps, steam, gas and oil motors, flour milling machinery, they have a well-established reputation. Some of the firms have their own branches in Russia with commercial and technical staff; they build factories in Russia or have understandings with some Russian works for the supply of certain parts of the machinery or of the contracts that cannot be profitably imported; they have experienced agents with their own assistant engineer and a staff of experts ready to submit plans and estimates, and, where necessary, to take over the erection; they will keep ready in Russia a stock of machines, such as pumps or dynamos, and get orders, say, for emergency work in mines, because they can supply more promptly than the Russian manufacturer. Other machines, such as oil or gas engines, they can generally supply promptly from Germany, and finally they are ready to give credit and guarantees. It wants a large trade to justify such expenses, and any attempt on these lines by a single firm, whose goods are not known here, is sure to be a failure. But what is beyond the power of a single firm may be within the reach of a combination. Comparatively few of the large engineering works have engineers that understand English. German is more frequently needed. Where, however, any special machinery is offered, which is likely to find a more general sale, and, therefore, requires advertising, the advertisement should be in Russian, as it will probably be read by foremen. A good translation and clear type is wanted.

Dimensions of machinery are best given in metric measure, though English inch measure is still frequently used in Russia, and is generally understood. Many factories still work to the English inch, but in the technical high schools metric standards are used. The Russian official measure of length is the arshine (28 English inches) or the sazen (7 English feet) used in the wood trade in building, &c. The Russian poud is the commercial standard of weight, and even to the modern Russian engineer comes more natural than the kilogramme.

In attempting to trade with Russia two difficulties must be faced; the first difficulty is that railways and Government works, the institutions that use the bulk of all engineers' products, are forced by law to purchase exclusively Russian-made goods—from a file to a main engine. Exceptions are only made when unavoidable, but rarely on account of price or of quality. The second difficulty is that trade must be done in face of an apparently prohibitive tariff. Notwithstnding this protective tariff, Russian works manufacturing machine tools and engines are not prospering. Many have closed down, others work with a chronic deficit in this department. The reason is partly to be found in the inexperience of the designing engineers, partly because the necessary high standard of workmanship is so far unattainable, but more particularly because of the limited and irregular demand, which prevents repeat orders or the introduction of more modern designs except by changing costly models before they are depreciated by use. Machine tools that require a high grade of workmanship, or of which the weight is small as compared with the workman's wage put into it, or machines which are being constantly improved, or for which repeat orders are not to be expected, are unlikely to be made in Russia. But all these machines should be made as light as is possible consistently with their efficiency, and in every case the quotation should be made without such of the more massive parts that can be easily made after its arrival in Russia. Thus, engines are purchased without flywheels, oil engines without bed or silencer, lifts without counterweights. For these parts drawings and, if necessary, templates or gauges are supplied by the manufacturers.

Every quotation should contain (besides an advertising description) price and terms of payment, also net and gross weights and shipping dimensions, to enable the prospective purchaser to calculate the cost. This is very frequently omitted, and causes avoidable correspondence and delay. Prices are generally given f.o.b. British port (preferably Hull), since it is only from there that there is a regular steamship service to Baltic and Black Sea ports. In dealing with firms that are not used to custom-house business, it will be better to give the price free on rail at the Russian port and also to arrange with the custom-house and shipping agent. German firms frequently quote free (duty paid) delivered to customers' inland station.

In the matter of credit, easy terms of payment very distinctly assist trade in Russia. Ready money is not plentiful, and a sale can often be made on credit, where the demand for net cash would put the order out of question. This does not refer quite so strictly to large machinery for engineering works (though even here it is frequently necessary) as it does to dealings with agents and more particularly with those referred to above. In every case a strict inquiry into the character and financial standing of the purchaser is necessary. If this is done, and the sale department is in the hands of a man experienced in Russia, I believe the money is as safe in Russia as anywhere. I know importers that do a very large credit trade in Russia and whose bad debts for any one year do not amount to 1 per cent. of the turnover.

Small machine tools that find a regular sale amongst the smaller factories, on estates, &c., are best handled through the medium of wholesale importers and shops that specialise in the sale of technical articles. Such importers are found in commercial centres, particularly in Moscow.

Far better than an importing agent or a casual traveller would be the opening of a sales office, say, as a limited company, in one of the centres, best in Moscow, that would combine the interests of a group of British manufacturers, be financed and controlled by these and managed by a man of trust and experience. The financial arrangement, distribution of expenses and profits could be managed, if only a number of manufacturers were convinced that the trade can be done. The group would have to cover such specialities as high-speed steam, turbine, gas and oil engines, a list of specialities in modern machine tools, also flour milling and foundry machinery, pumps, emery grinders, &c. It should not be necessary to have a stock of machines or exhibition stores in Russia. Such a sales office could be relied upon to do a trade and to look after the interests of the manufacturers far more satisfactorily than an agent. A number of foreign manufacturers have branches in Russia, but they are from that class of manufacturers whose trade demands the assistance of experienced engineers, such as the equipment of flour mills, electrical and heating engineering, transporters or aerial railways and such. They will supply plans and estimates and superintend the erection. In some cases, as for instance in electrical engineering or light railways, such branches will work in conjunction with a Russian factory, which supplies those parts of the contract which cannot be imported.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Digitized by Google

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bexhill.—For the year ended March 31 the income of the electricity department was £10,244, including £6,789 from the sale of current by meter (an increase of £354) and £2,948 from public lighting.

The total expenditure was £5.158 (increase £44) and gross profit was £5,086 (increase £445). Interest (£1,837), instalments of principal (£2,390) and depreciation (£236) came to £4,462, leaving net profit £624 (against £536 in 1908-9), out of which £220 was expended on meters and £435 on public lighting. The units sold were 562,150 (against 558,137), including 393,178 to private consumers, 1,056 by private contract and 167,916 for public lighting. There are 53 arcs and 368 incandescent pillars for street lighting, and the total maximum supply demanded was 474 kw. The total capital expended is £68,625, an increase of £1,459. The working cost was 2·2d. (against 2·19d.) per unit and the total cost 4·1d. (against 3·86d.), and the equivalent of 43,350 8 c.p. is connected (against 40,101).

Cleckheaton.—The total income of the electricity department for the year ended March 31 was £4,532 (against £4,557 in 1908-9).

Total expenditure was £2,789, including £2,082 cost of generation, and gross profit was £1,743. Interest on loans absorbed £776 and sinking fund £981, leaving a deficit of £14, against a profit of £51 in previous year. The total capital expenditure is £28,353, an increase of £1,888. The works cost per unit sold was 0·74d. (0·74d.), and the total cost (including capital charges) was 1·62d. (against 1·51d.). The equivalent of 17,479 8 c.p. lamps is connected (against 11,492 8 c.p.), and there are 88 motors (of 380 H.P.) against 52 motors (of 190 H.P.). The total maximum load was 500 kw. (209 kw. lighting and 309 kw. power), the same as in 1909. The number of units sold was 668,812 (against 716,443), including 52,723 for private lighting (against 49,709), 225,270 for power (against 290,483), 381,383 for traction (against 372,323), and 9,436 for street lighting (against 3,928).

In the report accompanying the accounts it is stated that £164. 12s. was charged to the department for the use of refuse for raising steam, compared with £253. 14s. 9d. last year, which was for two years' supply. The increase in the lighting and power consumers was well over the average, but the majority of the new consumers were connected during the last quarter of the year.

Doncaster.—The revenue of the electricity department for the year ended March 31 was £10,435, including £9,885 from the sale of current by meter for lighting and power and for traction.

Working expenses were £5,491 and gross profit £4,945. Interest on loans came to £1,515 and sinking fund instalments to £1,940, and after providing for amount added to sinking fund to make good deficiency in interest (£299) the balance (£1,223) was placed to renewal fund. The capital expended is £64,501, an increase of £1,615 over 1909.

Traffic receipts of the tramways department for the past year were £14,962, and the total revenue £15,172. The total working expenses were £11,186, leaving £3,986 to meet interest (£2,666), sinking fund instalments (£1,240), amount added to sinking fund (£265) and bank interest (£81), showing a deficit of £135. The capital expended is £91,395, an increase of £4,753. 3,411,522 passengers were carried, and 488,261 car-miles run; the percentage of working expenses to receipts was 73·7; the total number of units used was 602,045 or 1·22 per car-mile.

Glasgow.—The 18th annual report and balance-sheet of the municipal electricity undertaking for the year ended May 31 last) were recently presented to and adopted by the Corporation.

Gross revenue amounted to £245,960 (including £234,369 from sale of electric current by meter and £11,591 from public lighting). Working expenditure was £105,438, leaving £140,522. Out of this sum interest (£57,381) and sinking fund (£39,475) were paid. From the balance (£43,666), depreciation (at the rate of 4 per cent. upon the gross capital expended) absorbed £43,475, leaving a surplus of £191 on the year's working, against a deficit of £3,545 in 1908-9. The capital expended during the year was £96,707 and the total capital expenditure (less depreciation) stands at £1,853,434.

The committee recommend that the present rates of charging for current be continued, though a scheme is under consideration whereby domestic consumers may get a supply of energy from the lighting circuits for cooking, heating and other domestic purposes at a lower rate than the charge for lighting, the cost of separate wiring being avoided.

During the past year, 34,742,853 units of electrical energy were sold to private consumers (compared with 32,736,058 in 1908-9), including 15,087,680 units for lighting and 19,655,173 for power and heating. The number of consumers was 19,489, against 18,158, an increase of 1,331 or 7·33 per cent. The total number of motors was 4,851 (of 32,918 H.P.), against 4,292 (of 29,505 H.P.). There are 837 arc lamps and 24 incandescents for street lighting. The equivalent of 1,759,120 8 c.p. lamps is connected, against 1,637,187. The average number of units consumed by private consumers was 20·63 per lamp, against 21·17. The maximum load was 21,719 kw., compared with 21,585 kw. The extension to the boiler house at Port Dundas station has been completed, and a 1,000 kw. motor-generator has been erected at the Springburn sub-station. Six miles of feeders and 5 miles of distributors have been laid on the north side and four miles each of feeders and distributors on the south side of the river during the past year. The total statutory expenditure per unit sold was 1·33d. per unit (against 1·36d.) and the total cost (including depreciation was 1·61d. (against 1·73d.)

Portsmouth.—The accounts of the electricity department for the past year were submitted to the Council last week.

Coun. FOSTER said it was proposed to allocate £1,500 out of the profits in relief of rates. He explained that during the year £900 had been spent out of revenue upon works which should be charged to capital account. The old machinery was being kept as a reserve in case of breakdown. The reduction of revenue was due to a reduction in the charge for public lighting, and to the extended use of metal filament lamps. The average income per unit sold was 3·14d., compared with 3·26d.

Coun. MACTAVISH attacked the proposal to allocate a sum for the relief of rates. The sum, with the tramway grant, represented a 1½d. rate. He thought the committee should bring the light to the reach of the small householder.

Coun. STOBIE asked the Town Clerk if the surplus could not be distributed amongst the consumers. He did not see why those who had not contributed to the surplus should benefit by it.

The TOWN CLERK replied that the application of the money received was prescribed by Act of Parliament, and could not be dealt with in the manner suggested.

Ultimately, the accounts were passed.

Redditch.—The accounts of the electricity department for the year ended March 31 show capital expenditure £41,642 (increase £1,597), and £8,824 has been repaid out of £40,366 borrowed.

Revenue was £5,825 (increase £383), working and general expenditure £4,710 and gross profit £1,115 (against £215 in previous year). Interest and instalment of loans and balance brought forward (£451) required £3,133, and to meet this £1,750 has been taken from general district rate and £268 carried forward. Works costs were 1·20d. per unit (compared with 1·44d.), and total costs, exclusive of capital charges, 1·36d. (1·60d.). Consumers connected are 682 (increase 119), with 41,215 equivalent 8 c.p. lamps (increase 3,863). Units sold and used at works were 770,702 (increase 39,881).

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

ALDERSHOT District Council invite tenders for supply of one chain grate mechanical stoker to be delivered and fixed at their electricity works. Further particulars and specification from the electrical engineer (Mr. F. Garside), and tenders to the Clerk to the Council (Mr. W. E. Foster), Municipal Buildings, Aldershot, by 6 p.m., Tuesday, Sept. 6. See also an advertisement.

Tenders are invited up to Oct. 5 for the supply of 5,000 porcelain insulators to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

Tenders are invited for supply of telegraph and telephone cable (schedule No. 284) and insulators (schedules Nos. 373 and 374) to the Postmaster-General's Department, VICTORIA. Tender forms at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to noon Oct. 17 for the supply of telegraph and telephone instruments and material (as per schedules 1 to 9) to the Postmaster-General's Department in TASMANIA. Tender forms and specifications at the office of the High Commissioner, 72, Victoria-street, London, S.W. See advertisement.

LITTLEBOROUGH District Council invite tenders for the supply and delivery of alternating-current (single and three-phase) electricity

Digitized by Google

meters. Specifications and forms of tender from the clerk to the Council (Mr. Geo. H. Wild). Specifications may be seen (but not obtained) at the offices of the consulting engineers (Messrs. Hawtayne & Zeden), 9, Queen-street-place, London, E.C. Tenders, addressed to Mr. Wild, Council offices, Littleborough, by Tuesday, Sept. 13.

By command of the POSTMASTER-GENERAL tenders will be received until noon, Monday, Sept. 26 for supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles to be delivered at certain ports in the United Kingdom. Forms of tender from the Controller of Stores (Mr. G. Morgan), Stores Dept., G.P.O., 17-19, Bedford-street, London, W.C.

The POSTMASTER-GENERAL also requires tenders (by noon Sept. 26) for creosoting, &c., telegraph poles. Forms of tender, &c., from the Controller of Stores, 17-19, Bedford-street, London, W.C.

MANCHESTER Electricity committee require tenders by noon Sept. 8 for the supply of 1 sq. in. single conductor paper-insulated cable. Specifications, &c., from Mr. F. E. Hughes, Town Hall, Manchester.

The directors of the Powell Duffryn Steam Coal Co. (ABERDARE) invite tenders for stores, including electrical goods. Tenders to London office (101, Leadenhall-street, E.C.) by Sept. 12.

HACKNEY (London) Council want tenders by 7 p.m. Sept. 15 for extension of main switchboard. Specification from Town Clerk, Town Hall, Mare-street, N.E.

PONTYPRIDD Council want tenders by Sept. 5 for supply of l.t. rubber-insulated cables with lead or fireproof covering. Specification from the generating station, Treforest.

MOUNTAIN ASH Council want tenders by 10 a.m. Sept. 12 for 12 months' supply of electrical stores. Forms of tender, &c., from the Electrical Engineer.

SALFORD Corporation invite tenders for supply and delivery of a vertical steam-feed pump. Tenders by noon Sept. 12.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms at the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders will be received (up to 3 p.m. Sept. 13) by the Deputy Postmaster-General, MELBOURNE, for supply of 8,510 telephones. Local representation necessary.

The Deputy Postmaster-General, SYDNEY (N.S.W.), invites tenders (until 2:30 p.m., Oct. 5) for supply of 5,000 porcelain insulators. Local representation necessary. Specifications, &c., from 72, Victoria-street, London, S.W.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

The Calcutta Electric Supply Corpn. is prepared to receive tenders for supply, delivery and erection at their Cossipore station and sub-stations, CALCUTTA, of motor-generators, turbo-alternators and condensing plant. Copies of specifications, drawings and general conditions from the secretary (Mr. Francis R. Reeves), Salisbury House, London Wall, E.C., to whom tenders by 10 a.m. of Sept. 19.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

MOSTAR (Austria-Hungary) municipality will receive tenders until Oct. 1 for the installation of electric generating plant.

Tenders are required for supply of machinery and tools intended for the workshops of the Directorate of Hydraulic Works, Buenos Aires. Tenders to Dirección General de Contabilidad, BUENOS AIRES, by 3 p.m. Oct. 10.

Tenders will be received at the Junta Económica (Dirección del Material), Valparaiso, until 2:30 p.m. Sept. 30 for supply of three dynamos and searchlights and machines and tools for the naval station at TALCAHUANO (Chili). Particulars from the Junta Económica.

TENDERS RECEIVED AND ACCEPTED.

Morecambe Council received 16 tenders for supply of feeder pillars, and that of Boydell & Son was accepted. For the supply of arc lamp carbons 14 tenders were submitted, and the contract was let to G. Hill & Co.

Walthamstow Council have accepted the following tenders:—Hurst, Nelson & Co., six car bodies (with spring fenders), £1,860, and trucks £426; Brush Co., electrical equipments, £1,684; Bartlett & Sons, weighbridge, at £112.

Brighton Corporation have accepted the tender of Richardsons, Westgarth & Co. to supply pipes, valves, &c., to connect up the condenser of the new turbine (now being supplied by them) with Shoreham Harbour, for £870.

Bolton Electricity committee have accepted the tender of Newton, Chambers & Co. for a feed water tank.

The tender of J. T. Foggo has been accepted for wiring the new schools at Batley Carr, Dewsbury, at £100.

Dundee Corporation have accepted the tender of J. C. Keay for fitting up 500 electric stairlights at £323.

Pooley & Austin's tender has been accepted by Battersea (London) Council for a new feeder switchboard.

Ulverstone (Tasmania) Council have accepted the tender of Sullivan & Ashman (at £4,417) for supply and erection of a Babcock & Wilcox boiler, 80 H.P. Allen high-speed engine and 50 kw. generator, with booster and balancer (made by General Electric Co., Sweden), switchboard and battery of Tudor cells.

Commonwealth Tenders.—The Postmaster-General's Department, Melbourne, have accepted the tender of Siemens Bros. Dynamo Works for 1,640 tubular iron poles, as follows:—

600 poles, with two side plates, length 24 ft. (at £2. 6s. each), 432 ditto, length 26 ft. (£2. 19s. 3d. each), 280 ditto, length 28 ft. (£4. 18s.), 150 poles, with steady plate and bog plate, length 24 ft. (£2. 10s.), 108 ditto, length 26 ft. (£3. 4s. 9d.), and 70 ditto, length 28 ft. (£5. 3s. 8d.).

The Victorian Railways Department have placed an order with the Railway Signal Co. for 40 electric staff instruments at £1,526.

Turbo-Pump and Turbine Contracts.—Messrs. Jens Orten-Boving & Co. have recently received orders for "Victoria" turbo-pumps of the automatic balancing type, including

One pump to deliver 390 gallons per minute against 228 ft. head for the Delta (B.C.) municipality, one pump to deliver 600 gallons per minute against 60 ft. for Messrs. Takata & Co., Japan; one pump to deliver 125 gallons per minute against 196·5 ft. head for New Zealand Government railways; and two pumps each to deliver 250 gallons per minute against 184 ft. head for the Hydro-Electric Commission, Preston, Canada.

Water turbine plant orders include one unit of 250 H.P. at 28 ft. for Soma Denki, and one turbine of 165 H.P. at 165 ft. for the Motomiya Light Co., Japan (through Messrs. Dick, Kerr & Co.); one of 28 H.P. for Messrs. J. Hardie, Glasgow; one Böving patent oil pressure governor for the Hachinoche Hydro-Electric Co., Japan; one turbine of 165 H.P. at 165 ft. for the Motomiya Light Co., Japan (through Messrs. Dick, Kerr & Co.); one turbine of 135 H.P. at 61 ft. head for South Falls, Canada; two turbines of 565 H.P. at 27 ft. head, complete with Böving patent governors, for Farnham, Quebec.

BUSINESS NOTICES.

The Calcutta branch of Messrs. Crompton & Co. has been removed from 99, Clive-street to 13/1, Clive-row.

The works of the British Electric Calibrated Fuse Co. have been removed to Luton, Beds. Telegrams, Fuses, Luton; telephone, 278.

As the lease of their Chelsea works has expired, the Cowper-Coles Galvanizing Synd. have secured larger works at Stratford, known as the Magnet Galvanizing Works, Bow Bridge, E.

The Smoke Consumption Synd. (Ltd.), which controls the Cowper-Coles patents for the consumption of smoke, has erected a plant at Willesden for the manufacture of its "Caloriser" bricks. The syndicate is applying the caloriser bricks to water-tube as well as to Lancashire and Cornish boilers.

Messrs. Thos. E. Noakes and Thos. W. Dickson have acquired the goodwill of Thomas Noakes & Sons (Ltd.), including all the designs, drawings and patterns of up-to-date boiler and engine fittings and other specialities, and they will continue the business in future as Thomas Noakes & Sons. The new offices and warehouse are at 16, Whitechapel-road, E.

Plant for Sale.—Northampton Electric Light & Power Co., Northampton, advertise for sale two exhaust steam feed water heaters and two battery charging boosters.

Patents Development.—The owners of patents No. 23,501/1899, relating to "Improvements in vacuum table lighting," and No. 12,582/1902, relating to an "Improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Information from Messrs. Lloyd Wise & Co., 46, Lincoln's Inn Fields, London, W.C.

The proprietor of patent No. 19,979/1904, for "Improvements in magnetic wheels or electromagnetic motors" desires to enter into arrangements by way of licence or otherwise for exploiting and working same in this country. Apply to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, London, W.C.

"The Journal."—Part 203 of the "Journal" of the Institution of Electrical Engineers is now ready, price 5s. Particulars of contents are given in an advertisement.

Textile Institute Journal.—We have received a copy of the first number of the "Journal of the Textile Institute," which gives particulars of the movement for the formation of the Institute and of its inauguration in Manchester in April last. The number also gives a list of the officers, committees, foundation members, &c.

"Osrams" in a Synagogue.—The following is from a recent issue of the "Jewish World," and shows how far reaching is the popularity of the metal filament lamp. The Jewish fraternity are more than ordinarily conservative in regard to the introduction of modern ideas into their places of worship, but at Bradford the tempting claims of "Osrams" have broken down all barriers to the march of progress. This is, the General Electric Co. inform us, the first instance in this country of a synagogue being illuminated by metal filament lamps.

An installation of electric light has recently been added to the Bradford Synagogue, consisting of three six-light electroliers, carrying 50 c.p. "Osrams" in the body of the synagogue and two seven-light "Osram" candle lamps on the Menoroth, on the two sides for the holy arc, besides lamps in the organ loft and the two schoolrooms. They were lighted for the first time on Shevuoth, and proved a great success. The whole of the expense was defrayed by Mrs. Von Halle, in memory of her husband, who died last winter.

"Sistoflex" Pressspahn.—Messrs. Spicer Bros., 19, New Bridge-street, London, E.C., will forward a sample of their registered "Sistoflex" Pressspahn to anyone sending their trade card. Upon the face of this sample are printed particulars of the sizes and thicknesses in which the material is supplied for electrical insulation. The firm holds possibly the largest stock of Pressspahn in London. The sample which is being sent out is fitted with a hanger to be hung up for easy reference. Particulars are also given of other insulating materials, such as varnished cloth, paper, tapes, vulcanised fibre, defiance insulation (Leatheroid), pure manilla and red rope papers which this firm supply in high class qualities and at low prices.

The British Association.—The Great Central Railway runs a series of fast trains every day to Sheffield, some of these being non-stop until reaching that station. The fact that the British Association is this year meeting at Sheffield will give this information additional interest to many of our readers. The best trains from Marylebone are 8:45 and 10:0 a.m. and 12:15, 3:15 and 6:20 p.m., and returning to Marylebone from Sheffield 8:50 and 11:21 a.m., 3:27 and 6:21 p.m. (These have restaurant cars.)

Encyclopædia Britannica.—The University of Cambridge has acquired the copyright of the Encyclopædia Britannica, and is about to publish, at the University Press, an entirely new (eleventh) edition. A pamphlet issued by the syndics of the Cambridge University Press explains the circumstances which have led to this new departure in widening the educational labours of the University. The new edition has been constructed and will be published as a whole. There will be an India paper as well as an ordinary paper impression.

CATALOGUES, &c.

G.E.C. Apparatus.—From the General Electric Co. have come a number of pamphlets dealing with their specialities. These include the new Butt arc lamp described in last week's Electrician, the "Salford" type ironclad switchgear, Witton switches of various kinds, and oscillating fans suitable for running on either direct or alternating current.

Adnil Motors.—The Adnil Electric Co. have sent us a list in which are given particulars of motors from 3 to 68 h.p. and dynamos from 2·5 to 48 kw. Much useful descriptive and technical information regarding these machines is given in the pages of this catalogue. Particulars are also to be found regarding motor generators, flexible couplings and other similar accessories.

Thermometers.—Engineering Supplies (Ltd.) have ready a pamphlet illustrating and describing various types of industrial thermometers.

Electric Driving of Rolling Mills.—We have received from the Allgemeine Elektricitäts-Gesellschaft (Berlin) a list in which details of various rolling mills equipped by the company with the electric drive are given. Besides some impressive figures, illustrations showing the type of plant employed are also furnished.

BANKRUPTCIES, LIQUIDATIONS, &c.

The trustee (Mr. F. C. Brogden, 10, Bank-street, Lincoln) in the bankruptcy of Saml. Emerson Smith, electrical engineer, formerly trading at 271, High-street, Lincoln, has been released.

The trustee (Mr. E. Barlow, 1, Berridge-street, Leicester) in the bankruptcy of Wm. C. Ellis, electrician, Applegate-street, Leicester, has been released.

A first and final dividend of 3s. will be payable on Sept. 6 at 12, Cherry-street, Birmingham, to creditors of Herbt. J. Burdett, electrical engineer and contractor, 16, Regent-street, Rugby, and 32, Earl-street, Coventry.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

5,282 RENDLE & CHURCHILL. Holding submarine cables.
6,875 SIEMENS & HALSKE AKT.-GES. Semi-automatic telephone exchanges. (Date applied for, 18/3/09.)
9,832 WILSON & WILSON. Electric condensers. (Date applied for, 9/6/09.)

COMPANIES' MEETINGS AND REPORTS.

COMPANIA MARCONI DE TELEGRAFIA SIN HILOS DEL RIO DE LA PLATA (BUENOS AIRES).—The directors' report states that the expenditure for the past year was $24,640.15 gold and income $11,998.28, a loss of $12,641.87, which, with balance of $52,526.44 from previous year, makes a total of $65,168.31. The station at Punta del Este is working regularly, but in view of the increased shipping trade, it has been decided to instal new and more powerful apparatus there, with which it will be practicable to communicate with all vessels three or four days before arrival at and after departure from Buenos Aires. The station at Bernal has not yet been opened for public service, due to the delay by the Government in granting the necessary authorisation. The company has continued the preparations for direct communication with Europe, and, it is stated, only awaits reports from Mr. Marconi before commencing work on same.

MERSEY RAILWAY CO.—At the meeting on Friday Mr. James Falconer, M.P., said their receipts had increased during the half-year by £1,425 and expenditure had diminished by £1,274. Taking the working for the whole year ended June 30, receipts had amounted to £109,016, compared with £105,121. Working expenses amounted to £68,986, against £72,169, or a net gain for the year of £8,778 on the working of the railway. During the last half-year of steam working the number of passengers carried was 3,357,000; during the half-year with which they were now dealing they had increased to 7,395,000, an advance of 4,000,000 passengers. Passenger traffic had increased by 120 per cent. and receipts 85 per cent. The reason for the increase had been made apparent half-year after half-year, ever since, in fact, they had adopted electric traction, and no one could place a limit to the possibilities of their line if facilities continued to be afforded to the people to get to and from Liverpool to different parts of the Worral Peninsula. The train service of the Mersey Railway was unsurpassed in any other part of the country, and American people had told him that they had nothing to equal it in the United States.

UNION OTTOMANE (SOCIETE POUR ENTREPRISES ELECTRIQUES EN L'ORIENT).—This combination of German, Swiss and French capitalists has issued its report for the year ended June, which states that the past year was one of preparation. The principal business was the re-organisation of the Constantinople tramways, in which the company has acquired £153,000 in ordinary and £21,000 in preference shares. The tramway concession was prolonged (in 1906) to 1993, and the Union Ottomane hopes definitely to receive the order for the conversion of the lines to electric traction. The company also took part, in conjunction with the leading German and French electrical firms, in the competition for the establishment of electricity supply in Constantinople, and a decision is expected to be arrived at by the Ministry of Public Works by the middle of December at latest.

VERA CRUZ ELECTRIC LIGHT, POWER & TRACTION (LTD.)—At the meeting on Wednesday the chairman (Mr. V. W. Yorke) said that their anticipations had been realised. There had been a considerable increase in business, and a satisfactory saving had been effected in the costs of operation by the good results obtained from the oil engine plant. The net profits showed an increase of nearly 100 per cent. over those for 1908. There was an improvement in all three departments (power, lighting and tramways), and during the first six months of the present year they had still further increases in gross and net profits. The outlook for the future was very hopeful. They had just completed the installation of the additional arc lamps for public lighting, and the business in sight would enable the company to show a satisfactory increase in the profits for the current year.

NEW COMPANIES, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

CHILIAN CONSTRUCTION CO. (LTD.) (111,448.)—Reg. Aug. 25, capital £500,000 in £1 shares, to carry on the business of financiers, constructors of roads, railways, tramways, docks, &c., and any electric light, hydraulic and other public works. Private company. First directors, J. S. P. Samborne (chairman), C. Grenfell, J. E. P. Coyne and P. Burton.

T. & J. JACKSON (LTD.) (111,461.)—Reg. Aug. 25, capital £11,000 in £1 shares (5,000 preference, 5,000 ordinary and 1,000 deferred), to take over the business of electricians, electrical and mechanical engineers, machinists, dynamo and motor manufacturers, &c., carried on as T. & J. Jackson & Co. Private company. First managing directors, T. Jackson and J. Jackson. Reg. office, 14, Park-road, Regent's Park, London, N.W.

MORTGAGES AND CHARGES.

ELECTRICAL APPARATUS CO. (LTD.)—A memorandum of satisfaction in full on Aug. 19 of debentures dated Oct. 27, 1909, securing £500 has been filed.

COMPANIES INCORPORATED OUTSIDE THE U.K.

HOBART ELECTRIC MFG. CO.—Particulars filed Aug. 15. Capital stock $200,000 in shares of $100. Reg. at Troy (Ohio, U.S.A.) in August, 1897. British address: 1-3, Holborn-circus, E.C. Messrs. McIntyre & Capel Peters, solicitors, are authorised to accept service at 401, Birkbeck Bank Chambers, Holborn, W.C.

CITY NOTES.

MEMORANDA (Sept. 1).—**Bank rate 3 per cent. (since June 9, 1910). Price of silver,** 24⅛d. per oz. Consols 80⅞—81⅛ for money; 81⅛—81⅜ for account. **Consols Pay Day, Oct. 5; Stock and Shares Continuation Days, Sept. 13 and 27; Ticket Days, Sept. 14 and 28; Pay Days, Sept. 15 and 29; Mining Shares Carry Over Day, Sept. 12.**

PRICES OF METALS (London).—*Copper*, cash, 55¾; three months, 56⅜. *Lead*, English, 12¾—13; foreign, 12½—12¾. *Spelter*, 22⅜—22½. *Tin*, English, 157—158; foreign cash, 163; three months, 159. *Iron*, Cleveland, cash, 49/4½, three months, 50/3.

ASCOT DISTRICT GAS & ELECTRICITY CO.—The directors have declared an interim dividend at the rate of 5 per cent., less tax, for the past half-year.

BLACKPOOL & FLEETWOOD TRAMROAD CO.—A dividend of 4 per cent. has been declared.

BRITISH INSULATED & HELSBY CABLES (LTD.)—An interim dividend at the rate of 8 per cent. per annum has been declared on the ordinary shares for the half-year to June 30.

OXFORD ELECTRIC CO. (LTD.)—The directors announce an interim dividend at the rate of 6 per cent., less tax, on the ordinary shares for the past half-year, payable Sept. 14.

UNITED ELECTRIC CAR CO. (LTD.)—The directors have declared a dividend of 2½ per cent. for the year ended June 30.

NOTES.

Tariffs in Electricity Supply.

FEW Papers of practical interest to electrical engineers were presented to Section G of the British Association this year, and it is curious that the Paper of probably greatest importance to them—that by Mr. E. W. COWAN, on "The Price of Electricity"—was read before the section dealing with Economic Science and Statistics. Mr. COWAN apparently hoped to find here a more sympathetic audience than that provided by his fellow engineers, so that the support which his views received from such eminent engineers as Mr. S. L. PEARCE and Mr. W. B. WOODHOUSE should prove particularly gratifying to him. Mr. PEARCE, however, drew attention to the difficulty of converting principles into practical tariffs, which latter have always been the *bête noire* of supply engineers. The broad-minded policy advocated by Mr. PEARCE, of arriving at a fair price for power supply to large consumers by basing such charges on the present cost of installing additional plant, is one which we have from time to time defended; and although some classes of consumer, such as tramway undertakings and lighting consumers, frequently feel themselves unduly penalised, there is little doubt that the above policy is commercially sound. Commercial methods are being more and more introduced, although somewhat slowly, into electricity supply, so that a fixed relation between the price charged per unit and the calculated average cost of production will probably soon be considered of secondary importance. Nevertheless, the problem is not quite as simple as Mr. COWAN would have us believe. Electric energy generated for a particular purpose may sometimes be regarded as a by-product of the whole supply, just as hides may be regarded as a by-product of beef. But there is an important difference in the two cases. The animal kingdom unfortunately does not permit us to grow hides without beef, or beef without hides, whereas it is possible to generate energy for light without at the same time producing energy for power, and *vice versâ*. Consequently, the price of energy for power does not necessarily fall when the demand for light increases, whereas hides might become a drug on the market if people insisted on eating enough beef. Nevertheless it is a good thing to have these economic points discussed and we are glad that Mr. COWAN has read his Paper, which we hope will be studied carefully by all station engineers. It is a bad thing to have very set ideas on most subjects, and more flexibility in ideas on tariffs may lead to such a large expansion in electricity supply as would rejoice the heart of many an engineer.

Coasting on Electric Railways.

ANOTHER Paper in which considerable interest was taken by electrical engineers was that read before Section G by Mr. PHILIP DAWSON, on "The Electrification of the London, Brighton & South Coast Railway between Victoria and London Bridge." The main features of this line are well known to readers of THE ELECTRICIAN, but there was one point mentioned by the author to which reference may here be made, namely, the system of calling the attention of motormen to the most economical places at which to cut off current for coasting or for stopping at stations. For this purpose a St. Andrew's Cross has been painted on the ironwork at such points along the track. That considerable economy is possible where this method is adopted can be gathered from the fact that a saving of from 5 to

Digitized by Google

10 per cent. in the energy consumption has thereby been effected on the South London line. Although motormen may be instructed to handle their controllers effectively so as to economise in current consumption, the best results can obviously only be obtained by making such operation as automatic as possible, as in the above case, so that individual judgment is obviated. This is particularly important where frequent stops are necessary. That so large a saving is possible by such a simple expedient emphasises the importance of attention to detail.

Hysteresis Effect in Weston Cells.

In the report of the Electrical Standards Committee of the British Association, reference is made to hysteresis effects which occur in a small percentage of Weston normal cells. The report further points out that cells which exhibit marked hysteresis effects invariably change with time at a comparatively rapid rate. The cause of the hysteresis seems to be different from that observed, many years ago, in the case of the tube form of Clark cell, for in the latter case the irregularities appeared to be chiefly due to a difference of concentrations of the zinc sulphate solution at the anode and cathode. Inasmuch, however, as the Rayleigh H form of vessel is used for the Weston cell, a difference of concentration in the cadmium sulphate solution at anode and cathode is most improbable. We are informed that if a Weston cell, in which the hysteresis effect occurs, is raised in temperature, the decrease in E.M.F. is, in general, very nearly normal; but when, afterwards, the temperature is lowered, the increase in E.M.F. is abnormal. Although the changes have not yet been explained, users of cells will be interested to know that all cells sent for test at the National Physical Laboratory are examined for this hysteresis effect, and no certificate is granted if the effect exceeds a certain limit. For the purpose of the test the cells are kept at a constant temperature for a few days and their E.M.F. measured; afterwards, the temperature is increased 10°C. and the cells maintained at this temperature for 24 hours. The cells then cool in a normal manner to the initial temperature and after two days the E.M.F. is again measured. If this disagrees with the E.M.F. first observed by 0·0001 volt or more, the cell is regarded as abnormal and no certificate is granted. Fortunately, comparatively few cells fail in this test—in many cases there is absolute agreement between the initial and final values of the E.M.F. The whole matter is being investigated and the solution of it promises to clear up the sole remaining cause of disturbance in a few Weston cells.

Glow Lamp Tests.

In comparing the results obtained by laboratory measurements in different countries, a doubt has sometimes been felt whether the results were really comparable owing to possible differences in the standards employed. Any such doubts are now disappearing rapidly owing to more general agreement and to comparisons between the various national laboratories. One of the most recent steps of this kind relates to the testing of glow lamps, and is described in another column by Messrs. C. C. Paterson and E. H. Rayner. The object in view was to see if lamp tests carried out in England and in America in accordance with the specification of the Electrical Standards Committee would give the same results. For this purpose a dozen carbon lamps were prepared on each side of the Atlantic; half the English lamps were sent to America and half the American lamps were sent to England. The two batches of mixed lamps were then run for life tests at the National Physical Laboratory and at the Electrical Testing Laboratories of New York. One of the English lamps seems to have undergone a change between the time when it was tested at Teddington and its arrival at New York. But if this lamp is discarded and a correction is introduced for the slight difference in pressure at which the lamps were tested in the two countries, it is found that the difference in the average life obtained at the two laboratories does not exceed 2 per cent. This result is certainly gratifying, and may be said to be remarkably good for such a small number of lamps, even though "selected."

Accidents in Mines.

Some acute differences of opinion have been expressed by mining engineers from time to time, usually on the score of danger, on the subject of the application of electricity in the underground operations of coal mining. Certainly if such carelessness as was reported last week at the inquest held at Pencoed on a workman killed at South Rhondda Colliery were generally practised in coal mines, the views of those who hold that the installation of electric cables and apparatus in coal mines is likely to be dangerous would be justified. But it is difficult to understand how, in view of the regulations which obtain in connection with mining operations, or with most ordinary precautions such an accident could have happened in any mine. To leave disused wire lying about so that it may come in contact with live conductors is to invite disaster, and it is clear that a greater appreciation of the danger likely to result from such carelessness must be brought directly home to the men before a mine can be considered safe. Surely, however, this is no argument against the employment of electrical methods in a coal mine. Whatever system of working were adopted, loose wire would prove a danger in differing degree. That such danger is increased where electric cables are installed seems too obvious to need pointing out. If similar occurrences to that at South Rhondda Colliery become at all prevalent, the hands of the clock will certainly be put back in regard to the application of electricity in mining work. It therefore behoves all mining electrical engineers to take instant steps towards educating the men under them to a better appreciation of what may happen if electrical apparatus be not used in a proper way.

Isolation of Radium.—According to the Paris correspondent of "The Times," Mme. Curie and M. Debierne have just presented a joint memoir to the Académie des Sciences announcing that they have succeeded in isolating pure radium. The metallic radium which they have obtained is of a brilliant white colour, which blackens when exposed to the air. It burns paper, rapidly decomposes water, and adheres to iron.

Cable Interruptions and Repairs.

Electric Power in Stone Quarries.—According to the "Canadian Electrical News" the Point Anne Quarries Co. is considering the advisability of replacing its present steam-driven plant by electric motors. A certain number of motors have been used hitherto, but these will be considerably increased in number, and all the power required will be taken from the high-tension mains of the Seymour Power and Electric Co.

Brussels Exhibition Fire.—It is hoped that the King of the Belgians will open the reconstructed British Section of the Exhibition on September 15. The preliminary work in connection with the equipment of the new section has progressed so satisfactorily that there is little doubt everything will be completed by the above date. The Exhibitions Branch of the Board of Trade hope that the Brussels fire will not affect the chances of a representative exhibit at the Rome and Turin Exhibitions next year.

International Conference of Government Telegraph and Telephone Engineers.—The second conference of the International Association of Government Telegraph and Telephone Engineers commenced at the Sorbonne, Paris, on Monday, representatives from 22 Government Departments being present. M. Millerand, French Minister of Public Works, delivered the inaugural address, which dealt chiefly with the subjects of the standardisation of telephonic circuits and the development of automatic telephonic communication.

Cyrus Field.—We consider the family of the late Mr. Cyrus Field, a name famous in telegraph circles, have a legitimate complaint to make against the officials of the British Criminal Investigation Department, who selected for the man Crippen, charged with the murder and mutilation of his wife in London, the name of Cyrus Field during his journey across the Atlantic. The name is an uncommon one, and its adoption in this objectionable way must have caused a deep feeling of annoyance amongst the late Mr. Field's family and his numerous friends on both sides of the Atlantic.

German Central Station Statistics.—In a recent number of the "Elektrotechnische Zeitschrift" Mr. G. Dettmar gives some details regarding electric power stations in Germany, the figures referring to the period ended April 1, 1910. The total number of stations on that date was 2,358, and these supplied energy to 6,470 cities and towns. Their aggregate capacity was 1,373,000 kw. Of these stations 767 used steam, 214 hydraulic power, and 350 internal combustion engines, while 51 were transformer or converter stations. Fifty-two stations supplied single-phase current, 241 three-phase, and 1,736 continuous-current, while the remainder used some combination of these three systems.

Street Lighting in Westminster.—A controversy on this subject has recently been taking place in the columns of our contemporary the "Westminster Mail." In reply to a letter by Mr. E. Wilmot Seale, secretary of the Charing Cross, West End & City Electricity Supply Co., (which also appeared in our issue of August 26th), Mr. F. W. Goodenough, of the Gas Light & Coke Co., writes that it has been officially stated that the electric lighting in the St. George's district is costing £10,000 a year more than would efficient gas lighting, while he complains of the righteous attitude taken up by electrical engineers towards the gas prices. "When," he writes, "the St. James' Company reduced their price five years ago from £30 to £17 per lamp per annum to keep out gas, I do not remember much being said about 'considerations of advertisement and preference having an undue bearing on the composition of the prices tendered.'" In reply to this Mr. S. T. Dobson, chief engineer of the St. James' & Pall Mall Electric Light Co., writes :—

In correction of the statement in Mr. Goodenough's letter I would say that the St. James' Company was able to reduce the price five years ago from £30 to £17 per lamp per annum for the reason that during the nine years of the previous contract the sum of £5,000, representing the original capital expenditure, had been written off, and that the cost of electric supply in the district had been generally reduced. But the contract at £17 per lamp per annum was run at a fair profit, and on this account the Company has been in a position to supply the 16 flame lamps in Regent-street which have given such great satisfaction for the past 12 months at the same price of £17 per lamp per annum, and to replace the other 50 electric lamps on the circuit with similar lamps at the same price. This offer is clearly set out in a letter of the company to the City Council, dated April 21, 1910, and if it could have been accepted, the 66 electric lamps of the Regent-street type would have cost a total sum of £1,122 per annum, as compared with the total sum of £1,127 per annum which is to be expended on the corresponding gas lamps. But this special offer was barred out by the form of tender, and the subsequent proceedings, and there is no more to be said on that.

Current Topics.

Subjects of current interest dealt with in this issue include the following :—

Messrs. C. C. Paterson and E. H. Rayner contribute an article on "Comparative Life Tests on Glow Lamps." The tests have been carried out at the National Physical Laboratory and the New York Electrical Testing Laboratories.

We give an account of the proceedings at the meeting of the British Association at Sheffield, where, among others, Papers were read by Mr. Philip Dawson on "The Electrification of the London, Brighton & South Coast Railway between Victoria and London Bridge"; by Mr. E. W. Cowan on "The Price of Electricity"; by Prof. S. P. Thompson, F.R.S., on "The Laws of Electromechanics"; and by Prof. E. Wilson and Mr. W. H. Wilson on "A New Method for Producing High-tension Discharges." Among the reports presented were those of the Electrical Standards Committee and the Committee on Electro-Analysis.

Dr. W. H. Eccles contributes an article on "Recent Patents in Wireless Telegraphy."

We analyse the accounts for the year ended May 31st last of the Glasgow Corporation electricity department.

Bootle Council have applied for sanction to a loan of £8,500 for extensions of their electricity undertaking.

The Allgemeine Elektricitäts Gesellschaft, Berlin, have purchased the dynamo factory of the Felten & Guilleaume-Lahmeyerwerke at Frankfort.

On another page we give an abstract of the new Transvaal Power Act.

Coventry City Council have appointed a special committee to consider the advisability of purchasing the local tramways.

The accounts of Bradford tramways department show a nett profit of £32,365 for 1909-1910.

The power house of the Northern Light, Power & Coal Co. was completed on August 24th, and electrical energy is being transmitted to Dawson City (British Columbia), a distance of 44 miles.

An interesting report of the City Electrical Engineer on the past year's work of the Aberdeen electricity department is abstracted in another column.

Municipal Electricity Supply Extensions.—Halifax Corporation decided on Wednesday to put down additional generating plant at a cost of over £10,000.

INSTITUTIONS AND SOCIETIES.

The Institution of Gas Engineers.—The visit of the German Association of Gas and Water Engineers to Great Britain, which was postponed on account of the death of King Edward, has now been arranged to take place during the week commencing October 2nd next. The visitors are to be the guests of the Institution of Gas Engineers, the Gas Light & Coke Co., the South Metropolitan Gas Co., the Croydon Gas Co., and the Corporations of Edinburgh and Glasgow respectively. The engineer of the gas department of the latter city, Mr. Alex. Wilson, is now the President of the Institution of Gas Engineers.

The Association of Mining Electrical Engineers.—A meeting of this Association, which will be held with a view to extending the membership in Scotland, will take place at the Grosvenor Restaurant, Glasgow, on Saturday, September 17th, at 6 p.m. The Association of Mining Electrical Engineers has been founded to consider means for minimising the risks attending the application of electricity to the industry of mining; to promote the adoption of improved methods and devices tending to increase safety; to promote the general advancement of electrical science in its application to the industry of mining; to facilitate the exchange of information and ideas on this subject among the members of the Institution and otherwise; and generally to extend the experience, increase the efficiency and elevate the status of those engaged in such applications. In view of probable legislation in the future, it is felt to be of great importance that the collective opinion of mining electrical engineers should be expressed upon any suggested regulations or rules, and that the Association should be afforded an opportunity of submitting evidence. The secretary is Mr. C. Saunders, of London-road, Derby.

GLASGOW CORPORATION ELECTRICITY SUPPLY ACCOUNTS.

In analysing the accounts of the Glasgow Corporation electricity supply department for the year ended May 31, 1909, we had to record a deficit of £3,545, due to unusual conditions. On the present occasion, however, in considering the accounts for the 12 months ended May 31, 1910, it is satisfactory to notice that a surplus is again shown by the undertaking. Although the output of units has not increased to the same extent that it did a few years ago, the sales of energy for the past year are greater by over two million units than in 1908-9. Of the total quantity sold, viz., 36,479,243 units, 15,087,680 units were used for private lighting, 19,655,173 units for power and heating, and 1,556,661 units for public lighting, whilst the remaining 179,729 units were sold by contract. The consumption of electrical energy by private consumers shows an increase of 6·13 per cent. compared with the previous year's figures. It will probably prove of interest to give the following details of the sales of energy with the price obtained. The large number of units sold at ½d. and ¾d. per unit is noticeable

Lighting.			
Shops, warehouses, offices, &c.	915	units @	8d.
" " "	7,885,833	" "	3½d.
" " "	3,613,578	" "	½d.
Domestic consumers, churches, schools	1,804,107	" "	3d.
Special lighting	1,711,764	" "	1½d.
" "	71,483	" "	1d.
	15,087,680		
Power and Heating.			
Power and heating	5,175,341	" "	1½d.
" "	9,011,794	" "	¾d.
Power	1,172,238	" "	1d.
"	4,295,800	" "	½d.
	19,655,173		

The following analysis of private consumers' demands should also prove instructive. The figures given in brackets are the corresponding number of consumers a year ago, whilst the increase or decrease in the output for each class of consumer, compared with the previous year's sales, is also tabulated.

	Max. Demand	No.		Consumpt. Units.	Comparison with 1908-9.	
Consumers under 1 hr.		3,537	(3,461)	790,305	Dec.	37,914
" " 2 "		2,919	(2,789)	2,474,197	Dec.	157,496
" " 3 "		1,545	(1,506)	2,181,078	Dec.	448,637
" " 4 "		695	(665)	1,459,549	Dec.	94,327
" " 5 "		305	(264)	1,020,080	Inc.	116,188
" over 5 "		375	(268)	2,606,315	Inc.	473,103
Theatres, halls and schools		289	(231)	1,158,633	Inc.	3,952
Special		102	(59)	1,711,764	Inc.	239,062
Domestic consumers and churches.		6,417	(5,928)	1,685,759	Inc.	10,737
Power		2,630	(2,504)	19,438,936	Inc.	1,826,453
Heating		340	(265)	216,237	Inc.	75,674
		19,154	(17,940)	34,742,853	Inc.	2,006,795

One of the most interesting points brought out by the above tabulation is the decrease in consumption by "short hour" and what may be called "medium hour" consumers; and this in spite of a considerable increase in the number of consumers. Perhaps the most gratifying feature is the increase in the sales of energy for heating, the increase of 75,674 units representing 54 per cent. of the previous year's output. In this connection it is interesting to notice that the Electricity Committee are at present considering a scheme whereby domestic consumers may obtain a supply of electrical energy from their lighting circuits for cooking, heating and other purposes at a lower rate than the charge for lighting, the cost of separate wiring being avoided.

Considerable expansion is also shown in power supply, the number of units sold having increased by 1,826,453, whilst 126 new power consumers were connected. In this connection it may be mentioned that the total number of motors supplied from the Corporation mains on May 31st last was 4,851, with a total horse-power of 32,918, compared with 4,292 motors and 29,505 H.P. at May 31, 1909. In seven instances transforming plant has been placed on consumers' premises. The total capacity of such private sub-stations is now 4,000 H.P.

In addition to the large expansion in power supply, the other main increase in the above table is about 600,000 units in the consumption by long-hour consumers. The number of units used by private consumers per lamp installed averaged 20·63, compared with 21·17 last year, but this figure is not very reliable as consumers frequently make alterations in lamps without notice. The figures are based on the number of 8 c.p. lamps or the equivalent in other devices, the total connections at May 31, 1910, being equivalent to 1,759,120 lamps, an increase of 121,933 during the 12 months. The number of public arc lamps in use at May 31st last was 837, the same as last year, but 24 incandescent lamps have been added during the year. The mains department have laid during the twelve months 10 miles of feeder cables and 9 miles of distributors.

Turning now to the distribution of the energy, 43,245,524 units were generated; of this total, 2,368,359 units were used on the works; 36,479,243 units were sold, and the remainder, viz. 4,397,922 units, or 10·17 per cent. of the total, were expended in distribution or unaccounted for. As will be seen from our analysis of the expenditure below, small economies have been introduced in the cost of generation and distribution, and the total costs also stand at a lower level than in any previous year. The bulk of the output is now generated at Port Dundas station, 28,458,213 units being supplied from that works, 14,235,302 units from Pollokshaws-road station, and 552,009 from Kelvinside station. It is interesting to notice that the coal bunkers at Port Dundas have been extended so as to have a capacity of 7,000 tons, sufficient to keep the works going for a considerable period in the event of a strike or adverse weather conditions on the canal preventing delivery.

The following is an analysis of the expenditure during the past financial year, together with the cost of working per unit sold, both for last year and for 1908-9 :—

		Cost per unit sold. 1909-10.	1908-9.
Generating Costs.			
Fuel	£31,437	0·207d.	0·251d.
Oil, waste, water, &c.	2,635	0·017d.	0·019d.
Salaries and wages at station	14,747	0·097d.	0·098d.
Repairs and maintenance	8,547	0·056d.	0·045d.
Total Generating Costs	£57,366	0·377d.	0·413d.
Distribution Costs.			
Wages	£3,140	0·021d.	0·021d.
Repairs & maintenance of cables, &c.	5,036	0·033d.	0·037d.
Repairs & maintenance of meters, &c.	3,106	0·020d.	0·019d.
Total Distribution Costs	£11,282	0·074d.	0·077d.
Management Costs.			
Salaries	£6,266	0·041d.	0·042d.
Stationery, printing, &c.	1,192	0·008d.	0·007d.
General establishment charges	4,475	0·030d.	0·023d.
Total Management Costs	£11,933	0·079d.	0·072d.
Rents, rates and taxes	£21,161	0·139d.	0·144d.
Attending and repairing public and private lamps.	3,696	0·024d.	0·024d.
TOTAL COSTS (*ex.* capital charges)	**£105,438**	**0·693d.**	**0·730d.**
Capital Charges.			
Interest	£57,381	0·378d.	0·381d.
Sinking fund	39,475	0·260d.	0·253d.
Total Capital Charges	£96,856	0·638d.	0·634d.
TOTAL COSTS (*inc.* capital charges)	**£202,294**	**1·331d.**	**1·364d.**
Depreciation	£43,475	0·286d.	0·371d.
TOTAL RECEIPTS from all sources	**£245,960**	**1·618d.**	**1·711d.**
Balance (surplus)	£191	0·001d.	0·024d. (deficit)

The surplus of £191 has been transferred to the Reserve Fund, which amounts to £20,131. In regard to this surplus of £191, it must be noticed that the sum set aside for depreciation, £43,475, is almost £10,000 less than the amount provided in the previous year. The total of £43,475 is obtained by allowing 1 per cent. on the cost of land and buildings, 3½ per cent. on machinery, instruments, &c., 5 per cent. on accumulators, 2 per cent. on mains and cables and 4 per cent. on meters.

During the past year the capital expenditure amounted to £96,707, bringing the total capital expenditure (less depreciation written off) to £1,853,434.

DIRECT-CURRENT TURBO-GENERATORS.*

BY W. L. WATERS.

Summary.—The author outlines the present position of the direct-current turbo-generator, discussing the limits as regards speed and output. The type of brush to employ and the question of vibration are also considered.

While large power stations are gradually abandoning the use of direct-current generating apparatus, and generating instead alternating current for distribution to sub-stations, yet the number of small power stations and isolated plants generating direct current is increasing yearly. The advantages of the steam turbine set for such plants are smaller floor space and lower maintenance, due to absence of reciprocating parts. The difficulty in building a small steam turbine set is to design a direct-current generator which will operate satisfactorily at the high speed required for the economical operation of the turbine.

Direct-current turbo-generators have been built in Europe for the past 15 years, but their design and operation have not until recently been sufficiently satisfactory to recommend them for use under American conditions. The early direct-current turbo-generators were built with smooth-core armature and copper brushes, so that the operation was poor. Recently, however, several European manufacturers have been turning out direct-current turbo-generators in sizes up to 1,250 kw. and 4,000 amperes, which have proved much more satisfactory. All these machines operated with metal brushes and naturally suffered from the handicap of excessive maintenance cost. The result of this has been that European manufacturers are now adapting their machines, where possible, to operate with carbon brushes. American manufacturers realised early that the direct-current turbo-generator would never be a satisfactory commercial machine until it could be built with carbon brushes. But it is only within the last five years that the skill of designers and manufacturers has been equal to constructing direct-current generators to operate satisfactorily with carbon brushes at speeds materially higher than those of standard belt-driven generators. By careful design with auxiliary commutating poles and by accurate shop work it has been possible to build motor-generators for double the speed which was formerly considered possible, while the development of direct-current generators for coupling to steam turbines has proceeded under the same conditions. It can now be stated confidently that a direct-current turbo-generator has been developed suitable for satisfactory operation with carbon brushes under American conditions. They are now built in sizes from 10 kw. to 300 kw. at 125 volts and from 50 kw. to 500 kw. at 250 volts. Although 600-volt generators do not seem to be in great demand for this type of unit, yet a number have been in satisfactory operation for some time, notably a 1,000 kw. unit (consisting of two 500 kw. generators coupled to one steam turbine) operating at 1,500 revs. per min., which was installed by the North Shore Railway Co., California, in 1907.

Standard speeds which have been found most suitable for these generators vary from 6,000 revs. per min. for a 10 kw. 125-volt machine to 1,500 revs. per min. for a 500 kw. 250-volt type. All of these machines can be satisfactorily built to operate with commutating poles when carefully designed. Most engineers, however, seem to think that a commutating pole is a universal remedy for all commutating troubles. Experience with direct-current turbo-generators and other high-speed machines has shown that this is very far from being true. The commutating pole must be proportioned as carefully as the other parts of a machine, and it was the neglect of this fact which caused the failure and abandonment of this device when it was first used many years ago. The two factors which limit the design of direct-current turbo-generators are the commutation and the collection of large currents at high speeds. The commutating difficulties can be satisfactorily met in the generators given in the above list if a properly designed interpole construction is used. For generators of more special or more extreme ratings a complete system of distributed compensating winding in the pole faces should be used.

The limiting speed for which it is possible to build large direct-current turbo-generators is decided by study of the maximum commutator peripheral speed which can be employed with the particular grade of brushes adopted. The following equation limits the design of the commutator :—

Commutator peripheral speed = circumferential distance between brushes on the commutator × the number of poles × revolutions per minute.

*Abstract from "Engineering News" of a Paper read before the National Electric Light Association.

The minimum distance between brush-arms on the commutator which can be conservatively allowed for any given voltage, is definitely fixed by the conditions of mechanical clearance necessary for accessibility and to prevent flashing, and also by the space required for the necessary number of commutator segments per pole. The number of poles is decided by the current the machine is to commutate. The maximum commutator peripheral speed is decided by the type and quality of carbon brushes which are adopted, while the revolutions per minute should be fixed by the question of maximum economy for the steam turbine. Thus we have the above equation stating a rigid relation between a number of factors, each one of which is subject to restriction.

Flexible metal brushes will operate whether the commutator runs true or not; and, having low contact resistance, they are suitable for collection of large currents. This explains why they were adopted so universally on the early European machines. If the brushes are not carefully trimmed frequently, the trailing edge of a copper gauze or wire brush becomes ragged, and when the brush is in such condition a short-circuit or sudden violent change in load is liable to make the machine flash over. A new type of copper-leaf graphite brush has been used recently in Europe with better results, but the operation cannot be considered satisfactory, and the cost is high. Carbon-trailing tips have been used with metal brushes, but this means a complicated and sensitive brush gear, which is practically as difficult to manufacture and keep in operative condition as a brush gear using all-carbon brushes. The life of metal brush gear of all types is extremely short, so that the cost of renewals and the continual trimming which is necessary become prohibitive.

It is now apparent that the only satisfactory solution of the commutator problem on a direct-current turbo-generator, for American conditions, is the use of carbon or graphite brushes. It is an open question whether it is better to design these machines to operate with ordinary good quality graphite carbon brushes or with some special high-grade brush which must be obtained, for example, from Europe. With carbon brushes a commutator is required which runs absolutely true under all conditions and at all times. Commutators to carry a large current at high speed are always relatively small in diameter and long. The diameter is fixed by the revolutions per minute and the maximum peripheral speed, which can be satisfactorily operated with the particular grade of carbon used and with the degree of accuracy obtainable in commutator manufacture. The peripheral speed usually adopted at the present time in America is from 4,500 to 6,000 ft. per minute, although peripheral speeds 40 per cent. higher than this have been used by European manufacturers with a special grade of brush. With the diameter fixed, the length of the commutator is decided by the questions of temperature rise and correct spacing of the requisite number of brushes. When the length of the commutator would be greater than about 30 in. it usually becomes advisable to build two commutators of half the length instead of one full length. A difficulty which is experienced with any long commutator, or with two commutators in tandem, is the lack of uniformity in the distribution of current between the different brushes on each brush arm. It can be avoided only by careful selection of a suitable type of brush holder carefully fitted with good quality brushes and a suitable arrangement of generator leads.

The standard type adopted for direct-current turbo-generators is a cylindrical commutator of the shrink-ring type. Radial commutators have been used to a certain extent in Europe with good results, but the inaccessibility of the brushes has prevented their extensive adoption. The only advantage claimed for them is a reduction in over-all length and less trouble due to vibration of the armature caused by lack of balance. This reduction in vibration is due to the fact that the operating surface of the commutator is at right angles to the shaft, and consequently in the same plane as any vibration, instead of being at right angles to such a plane, as is the case with a cylindrical commutator.

The V-ring type of commutator is unsuitable for long-speed commutators of small diameter, as with this construction it is difficult to keep the mechanical stresses within reasonable limits. The advantage of the shrink-ring construction is that the stresses can be directly calculated and arrangements made to take care of them. The shrink rings are of high-grade steel and are of sufficiently heavy section so that the stresses due to centrifugal action are moderate. They will retain their circular form and prevent any local distortion of the commutator.

The standard cylindrical shrink-ring type of commutator is, in small sizes, built directly on the shaft, while in large sizes it is built on a bushing. The success or failure of a commutator depends upon extremely accurate shop work and a design such that the deflections and stresses due to centrifugal action and temperature variation are moderate. The micanite or mica used in the construction, instead of

Digitized by Google

being a heterogeneous combination of mica and shellac, must be built up of carefully gauged and selected mica segments of uniform thickness regularly arranged and cemented together with the minimum amount of shellac. This micanite has to be carefully treated so that it takes its final dimensions before being placed in the commutator. Every element in the commutator, that is, the copper, micanite, bushing and shrink rings, must be carefully gauged. After the commutator is assembled it must also be carefully seasoned, so that there remains no possibility of distortion or of change in the relative position of segments after the machine is placed in operation.

The mechanical construction of the armature is also of great importance, since it is essential that the balance of the armature should not change after the machine is put in operation. This necessitates that the punchings do not get loose or move on the shaft and that the armature winding does not move under the action of centrifugal forces. The punchings are usually either pressed on the shaft one at a time or built up on a mandrel bored out and shrunk on the shaft, no intermediate spider being used on account of the small diameter. Opinion varies as to whether the armature coils are better held in position by wedges or by wire bands, but the most satisfactory arrangement seems to be the use of bands on the small and wedges on the large armature. The end connections on the armature are probably better held in position by steel wire bands. Bronze shrink rings have been used for this purpose, but there is danger that they may get loose and change the balance of the armature, as it is very difficult to fix them securely. The question of insulation of the armature winding is extremely important. The insulation on the armature coils must be carefully baked and pressed, so that there will be practically no shrinkage and consequent movement of the coils. The armature winding is exposed to carbon and copper dust from the commutator, and the collection of dirt on such a high-speed armature is also very much greater than on the corresponding low-speed. On account of this it is necessary to be extremely careful in insulating all bare metal on the armature, so that there will be no danger of " flashing over " across dirty surfaces to the earthed parts.

The question of vibration is one of the most serious difficulties to be considered. It is difficult to determine the critical speed of a direct-current turbo-generator armature; but it is extremely important that this speed of the generator when coupled to the steam turbine shall not be close to the normal running speed. This usually means that the armature must be designed with the maximum possible diameter of shaft, and it is generally necessary to sacrifice the advantage of low commutator peripheral speed to enable a sufficiently stiff shaft to be used. The question of permanency of balance is equally important, and this requires that there be no relative movement of the component parts of the armature, and also that the shaft neither springs nor deflects under the influence of the temperature variations obtained. Direct-current turbo-generators as built a few years ago would operate perfectly on test when first built, but, after running six months, mechanical vibration and deterioration of the commutator were likely to be so great that they could no longer be considered commercial.

One of the most satisfactory constructions for small units is a two-bearing set, the turbine wheel being overhung and the two bearings self-aligning. This construction obviates any trouble due to lack of alignment. With larger units, however, it is no longer suitable on account of the axial space required by the turbine, and a three or four-bearing set with a coupling becomes necessary. Such sets again require careful alignment and careful fitting of the coupling, otherwise there will be trouble with vibration. Oil-ring lubrication is effective in the smaller sizes, but forced-flow lubrication is usually required above 100 kw. if the temperature of the bearing is to be kept within reasonable limits and if the operation is to be reliable.

Foreign practice is usually to enclose completely all the armature, except the commutator, and to supply cooling air from a special duct. Here we do not consider this advisable because of difficulty of access. The usual practice on small machines is to employ a semi-enclosed construction with natural cooling. On large machines, however, as the noise is appreciably more than in corresponding low-speed machines, it may ultimately be found advisable to adopt a more enclosed construction.

At the present time the direct-current turbo-generator can hardly be considered commercial above 500 kw. at 250 volts, and the probability is that in larger sizes it will be necessary to use an alternating-current turbo-generator and rotary converter as a substitute. This substitute may, however, be only temporary in the 750 kw. and possibly the 1,000 kw. sizes. Considerably larger sizes are at present in use in Europe, but it should be remembered that operating conditions there are by no means as severe as here, so that machines which would operate satisfactorily there might fail here.

PRINCIPAL MIERS' ADDRESS TO SECTION L OF THE BRITISH ASSOCIATION.*

I propose first to consider some general relations between teachers and their pupils, and then explain what, in my opinion, should be the change in the method of teaching, or at any rate in the attitude of teacher to pupil, which should take place when the scene changes from school to university.

First as to general relations between teachers and their pupils. Among all the changes and varieties of system and curriculum there is one factor which remains permanent and which is universally confessed to be of paramount importance—the individuality of the teacher and his personal influence upon the pupil. Personal influence is, of course, not only a matter of intellectual attainments; it appears to me, however, that at the present time so much is made of the duty of schools to aim at the formation of character that there is an unfortunate tendency to regard this duty as something distinct from the other functions of a master, and as independent of intellectual qualifications. Among the first qualities now demanded of a master in a public school for boys are manliness, athletic skill and a hearty and healthy personality, and these are often regarded as compensating for some lack of intellectual equipment. I suspect that there is a similar tendency in schools for girls. And yet I think it will be found that the only permanent personal influence is really wielded by teachers who exercise it through intellectual channels, and that those who acquire intellectual authority will generally succeed in training the characters as well as the minds of their pupils. On the other hand, the master who is not up to the proper intellectual standard will soon be found out by his cleverer pupils, and will lose influence, whatever may be the charm of his character. The formation of character so far as it can be distinguished from intellectual training, is largely worked out by the boys themselves in any public school in which healthy tradition and a sound moral atmosphere are maintained, although it is true that these traditions depend upon the character and personality of the teachers.

How is the proper personal and sympathetic relation to be established between teacher and pupil so that the individuality of the one may call out the character and the effort of the other? Those who enquire of their earliest school reminiscences will probably recollect that the teachers who obtained a real hold upon them did so by virtue of the power which they possessed of arousing their intellectual interest. In the young child I believe that this interest will be found to be mainly that of novelty. With an older student it is not enough that the impression or the idea should be new; if it is to arouse interest it must also direct his mind to a purpose. This distinction may guide us in differentiating university methods from school methods of education. Many of our failures are due to one or both of two prevalent mistakes. The first, the mistake of teaching children by methods that are too advanced; the second, that of teaching university students by methods that are better adapted for school children. It is with the latter that I wish to deal in this address; but we may in passing remind ourselves that when young men and young women are sent straight from the university to teach children with nothing but their university experience to guide them, it is not surprising that they often proceed at first on wrong lines, and as though they were dealing with university students.

Granting, then, that there should be a radical difference between the ways of school and university teaching, and that there is at present an unfortunate overlapping between the two, let me next consider how the distinction between the intellectual interest of a child and the intellectual interest of a man may guide us in adjusting our methods of teaching when students pass from school to the university. A tenable, perhaps even a prevalent, view concerning a liberal school education is that its chief purpose is not so much to impart knowledge as to train the mind. In any event, if the scheme of intellectual training be adequately fulfilled, the period of mental discipline should come to an end with the close of school life, and the mind should then be able to enter upon new studies and to assimilate fresh knowledge without a prolonged continuation of preparatory courses. Indeed, the professed object of entrance examinations to the university is to exclude those whose minds are not prepared to benefit by a course of university study. An entrance examination, then, should not be merely a test of whether a boy or girl has learnt sufficient of certain subjects to continue those subjects in particular at the university; and yet it has, unfortunately, come to be regarded more and more as performing this function, instead of being regarded as a test whether the student is generally fit to enter upon any university course. The result is that an entrance examination tends to become

* Abstract of the presidential address delivered last week at Sheffield by Principal Miers, D.Sc., F.R.S., to the Educational Science Section.

Digitized by Google

a test of knowledge rather than a test of general intelligence; merely one in an organised series of examinations which endeavour to ascertain the advancing proficiency in a limited number of subjects, and therefore tend really to encourage specialisation. Specialisation is not to be prevented by insisting on a considerable number of subjects, but rather by teaching even one subject in a wide spirit. Another result is that the entrance examination belongs properly neither to the school course nor to the university course; if it is taken at the age of 16, the remainder of the school career tends to be devoted to university work, which should not really be done at school; if it is taken after leaving school this means that work is being done at, or in connection with, the university which ought to be done at school. It is certainly true that for various reasons a vast deal of education is now being carried on at the universities which should belong to school life, and, moreover, is being carried on by methods which are identical with those pursued at school. It is equally true that, owing to the early age at which matriculation examinations or their equivalents may be taken, many schools are now asking that at the age of 18 or 19 a school examination may be held which shall be an equivalent, not for matriculation, but for the first degree examination at the university. This would really imply that schools should be recognised as doing university work for two years of their pupils' careers—surely a most illogical procedure, and one which supports my contention that there is now very serious overlapping, for it assumes that the work for the first degree examination can be carried on either at the school or the university, and therefore that there is no difference in the methods of the two. An increasing number of candidates actually present themselves from secondary schools for the external intermediate examination of the University of London; in 1904 there were about 150, in 1909 there were nearly 500 such candidates.

The whole matter is inextricably involved with the question of university entrance examinations. It must suffice here to say that I have been led to the conclusion that matriculation examinations should be designed to suit the capacity of average pupils not less than 17 years of age, if they are to test the intelligence of those who are ready to enter upon a university course.

Starting with the principle that the period of mental discipline is closed at the end of the school career, and that those who pass to the university come with fair mental training and sufficient intelligence, what should be the relation of university teaching to that which the student has received at school? Under present conditions the schools which aim at sending students to the universities endeavour to give a general education which will fit their pupils to enter either upon a university course or upon whatever profession or occupation they may select on leaving school. They do not confine the teaching of any pupil to preparation for a special profession or occupation, and they do not generally encourage special preparation for the university. Now contrast what happens to the pupils leaving such a school to enter a profession or business with what happens to those who proceed to the university. The former pass into an entirely different atmosphere; they are no longer occupied with exercises and preparatory courses which serve a disciplinary purpose; they are brought face to face with the realities of their business or profession, and, though they have to gain their experience by beginning at the lower or more elementary stages, they do actually and at once take part in it. The university student, on the other hand, too often continues what he did at school; he may attend lectures instead of the school class, but neither the method nor the material need differ much from what he has already done. Should not the break with school be as complete for him as for his school-fellow who goes into business? Should he not be brought face to face with the actualities of learning? After his years of preparation and mental drill at school, should he not, under the direction of his university teachers, appreciate the purpose of his work and share the responsibility of it?

Take science, for instance, as an illustration. In science there should be all the difference between the school exercises, on the one hand, which teach the pupil the methods of experiment, illustrate the principles laid down in his text books, and exercise his mind in scientific reasoning; and, on the other hand, the university training, which sets him on a course involving the methods of the classical researches of great investigators and a study of the original Papers in which they are contained, illuminated by the views of his own teacher. He also should awaken to the necessity of modern languages. A boy who, on leaving school, passes not to the scientific laboratories of a university, but to a scientific assistantship in a business or Government department, will very soon find it necessary to go to the original sources and acquire a working knowledge of foreign languages. It is regrettable that under existing conditions a scientific student sometimes passes through his university without acquiring even this necessary equipment. I believe this to be largely due to the fact that he is compelled to spend so much of his time in preparatory work of a school character during the early stages of his university career.

The spirit of inquiry which drives the literary student to find for himself the meaning of an author by study and by comparison of the views of others is really the same spirit of inquiry which drives the scientific student to interpret an experiment, or the mathematical student to solve a problem. Only by kindling the spirit of inquiry can teaching of a real university character be carried on. Give it what name you will, and exercise it in whatever manner you desire, there is no subject of study to which it cannot be applied, and there are no intelligent minds in which it cannot be excited.

The first question which a university teacher should ask himself is, "Am I rousing a spirit of inquiry in my pupils?" And if this cannot be answered in the affirmative it is a confession that the university ideal is not being realised. Some assert that this principle should also guide school education, and that it should be the first aim of the school teacher to stimulate the spirit of inquiry. My own view is that with young children this should be less necessary; they all possess it, and are by nature inquisitive. It should rather be the object of the teacher not to spoil the spirit of inquiry by allowing it to run riot, nor to stifle it by making the work uninteresting; if the lesson interests them, their inquisitive minds will be quick enough to assimilate the teaching.

I have often thought it an interesting parallel that among original investigators and researchers there are two quite distinct types of mind, which have achieved equally valuable results. There is the researcher who pursues an investigation with a constant purpose, and to whom the purpose is the inspiration. But there is also the investigator who has preserved his youthful enthusiasm for novelty and has in some respects the mind of a child; passionately inquisitive, he will always seek to do something new, and very often, like a child, he will tire of a line of research in which he has made a discovery, and take up with equal enthusiasm a totally different problem in the hope of achieving new conquests. The latter is, perhaps, the most fertile type of original investigator, but it is not the type that produces the best teacher, except for very exceptional and original-minded students; and such teachers do not often found a school of learning and research endowed with much stability. For ordinary students the investigator who pursues his researches as far as possible to their conclusion is the safer guide.

It will now be clear that the principle which I am advocating is a very simple one—namely, that the business of direct mental training should be finished at school, and that at the university the trained mind should be given material upon which to do responsible work in the spirit of inquiry. Preparatory exercises belong to school life and should be abandoned at the university. All this seems so obvious that it might appear to be hardly worth saying, were it not that the methods which actually prevail are so far removed from this ideal. When, for example, a boy who has not learnt Greek or chemistry at school comes to the university and proposes to take up one of these subjects he is generally put through a course of exercises which differ in no essential respect from those which are set before a boy of 12. In other words, our university method for the trained mind does not really differ from our school method, which is supposed to be adapted to the mind in course of training.

It may be asked, In what manner is this change to be introduced, and how is it possible under present conditions, where so many students are all pursuing ordinary degree courses and have no time or opportunity for special work, to provide teachers who can educate them in this spirit, if it is also their duty to get pass students through their examinations? The answer, I think, is that in a university the professors and higher teachers should be, without exception, men who, whatever may be their teaching duties, are also actively engaged in investigation. Their assistants should be teachers who, even if the whole or part of their time is occupied in routine teaching, have yet had some experience in, and possess real sympathy with, modern advanced work under such professors. This is only to be secured by insisting that teachers in a university should all have had some experience of original work. Under the present system at most universities, unless the student has been fortunate enough to come in contact with a teacher imbued with the spirit of research who is carrying on his own investigations, it rarely happens that he has the time or the means which would enable him to obtain any insight into the meaning of investigation before he leaves to take up teaching work. The need of post-graduate scholarships for this purpose is very widely felt, and is now frequently expressed. To insist upon such qualifications for all university students is, of course, under present conditions, impossible; but there should be no insuperable difficulty in insisting upon them for those who are to be allowed to enter a university as teachers.

Researchers are born, not made, and it is not by any means desirable that all university students should be cast adrift to make

Digitized by Google D

new researches and seek discoveries even under the direction of experienced teachers and investigators. This must depend to some extent upon the character of the pupil as well as of the teacher. The mere publication of Papers may mean nothing, and much that is dignified with the name of research is of no account. To turn a lad on to research, unless it be in the right spirit, may be only to set him a new exercise instead of an old one; to leave him to prosecute an investigation for himself may be to condemn him to disappointment and failure. On the other hand, to carry on any piece of work, whether it be new or old, in the zealous spirit of inquiry, with faith in a purpose, is to ensure the intellectual interest of the student; and I cannot see why this spirit should not animate all university education, whether it be accompanied by original research or not. The essential condition is that the chief university teachers should themselves create an atmosphere of investigation. So deep-seated is the belief that nothing must be undertaken without a preparatory course of training that even the best and most brilliant students are frequently discouraged from undertaking a new study until they have been subjected to the mental discipline of an elementary course in it.

The distinction that I have in my mind between university and school teaching may be expressed in this way. At school no subject should be taught to a class as though it were intended to be their life work. To take an example: It too often happens at present, owing really to excessive zeal on the part of school teachers, that mathematics is taught as though each member of the class were destined to become a mathematician; consequently only the few scholars with a real aptitude for mathematics become interested, and the remainder are left behind. On the other hand, at the university each subject should be studied as though it really were the life work both of teacher and student. Thus, to take the same subject as an illustration, the mathematical student will attend the full courses of his professors and will follow them with the interest of a mathematician; whereas for the scientific student it will only be in those branches of mathematics which concern him that the interest of his special science will put him on terms of equality with the mathematical student.

I have endeavoured to confine myself to the subject of university education, and not to say much, except by way of contrast, concerning school teaching. I must, however, return to it for a moment to emphasise the danger of that specialisation which, since it takes place at school and not at the university, is bound to be narrow, and which is often encouraged in pupils of special aptitude preparing for university scholarships. That a boy or girl should for a year or even two years before leaving school be practically confined to one subject, and should before entering the university be examined in that alone, appears to me to be contrary to all the best traditions of school teaching, and to the often expressed desire of the universities to ensure a good general education in those whom they admit.

What should be the exact nature of the teaching before and after the age of 16 or 17 for the mass of ordinary boys I would prefer to leave to the decision of those who are best able to judge. I think it highly probable that there should be a considerable alteration of curriculum at the critical age. But, if a break and change of subject are required at this age, I believe that a yet more complete change is required at the later stage when the boy goes to the university, and that school methods should then be entirely replaced by university methods—not because there is then a natural change in the mental powers of the student, but because it is the obvious stage at which to make the change if we are to abandon preparatory training at all. Should it be proposed that the change ought to be made at 16, and that after that age something of the nature of university methods should be gradually introduced, my fear is that this would only lead to the perpetuation of school methods at the university.

An interesting question which deserves to be very seriously considered is the question, What sort of school education affords the best preparatory training for the university? I have often heard it asserted that, if a boy is capable of taking up at the university a course which is entirely different from his school course, he will generally be found to have come from the classical side, and not from the modern side. An ordinary modern-side boy is rarely able to pursue profitably a literary career at the university, whereas it often happens that ordinary classical-side boys make excellent scientific students after they have left school. I am bound to say that this, is, on the whole, my own experience. It suggests that a literary education at school is at present a better intellectual training for general university work than a scientific education.

There are no doubt many causes which may contribute to this. In some schools the brighter boys are still retained on the classical side, while those who are more slow are left to find their way to other subjects; and some whose real tastes have been suppressed by the uniformity of the school curriculum turn with relief to new studies at the university and pursue them with zeal. But the facts do also, I think, point to some defect in the present teaching of school science whereby a certain narrowness and rigidity of mind are rendered possible. This may be partly due to the lack of human interest in the teaching of elementary science; the story of discovery has a personal side which is too much neglected, though it is more attractive to the beginner and might with advantage be used to give some insight into the working of the human mind and character. Moreover, it would form an introduction to the philosophy of science, which is at present so strangely ignored by most teachers.

But another noteworthy defect is the absence of that mental exercise which is provided by the thoughtful use and analysis of language. I believe that the practice of expressing thoughts in carefully chosen words, which forms so large a part of a good literary education, constitutes a mental training which can scarcely be surpassed, and it is unfortunately true that in the non-literary subjects too little attention is paid to this practice. In school work and examinations a pupil who appears to understand a problem is often allowed full credit, although his spoken or written answer may be far from clear. This is a great mistake. A statement which is not intelligibly expressed indicates some confusion of thought; and, if scientific teaching is to maintain its proper position as a mental training, far more attention must be paid to the cultivation of a lucid style in writing and speaking.

Although it is true that the intelligent reading and study of the great masters should assist in the acquisition of a good style, it is equally true that, if they come to be regarded as a school task, they are not viewed with affection, especially in these days of crowded curricula, when there is little leisure for the enjoyment of a book that requires deliberate reading. The art of expressing one's ideas in simple, straightforward language is to be acquired not so much by study as by practice. Much would be gained if boys and girls were constantly required to express their own meaning in writing. The set essay and the précis play a useful part, but do not do all that is needed. Translation does not give quite the necessary exercise. What is required is constant, with certain periods of conscious, practice, and that is only to be obtained by making every piece of school work in which the English language is used an exercise in lucid expression. Very few paragraphs in anything written by the ordinary schoolboy—or, for the matter of that, by the ordinary educated Englishman—are wholly intelligible, and teachers cannot devote too much pains to criticising all written work from this point of view. If we first learnt by practice to express our meaning clearly we should be more likely to acquire the graces of an elegant style later. I must add that I believe the training in the manipulation of words would be improved if all children were required to practise the writing of English verse—not in efforts to write poetry, but narrative verse used to express simple ideas in plain language.

The tutorial classes for working people which have now been undertaken by several universities, and which already number about 1,200 students, offer an opportunity of dealing with a body of intelligent and enthusiastic students who have not received the conventional training for a university course. Here, if anywhere, the difference between school methods of teaching and university methods ought to be apparent; and I feel sure that, if university teachers attempt conventional methods with these students they will be condemned to failure. It is certain that these classes will increase enormously and rapidly, and I have great hope that they will for this reason influence the methods of university teaching in a very healthy manner.

The acquisition of knowledge and the training of the mind are two inseparable aims of education, and yet it often appears difficult to provide adequately for the one without neglecting the other. I think, however, the fundamental question is to a large extent one of responsibility. Left to himself, a boy or a man will acquire a knowledge of the things which interest him, and will obtain a training from experience such as no school or college can give. If the teacher bears the responsibility during the period of school training, should not the student have a large share of responsibility in the quest of knowledge at the university? Now, it is of the essence of responsibility that there should be something sudden and unexpected about it. If, before putting a young man into a position of trust, you lead him through a kindergarten preparation for it, in which he plays with the semblance before being admitted to the reality, if you teach him first all the rules and regulations which should prevent him from making a mistake, you will effectually smother his independence and stifle his initiative. But plunge him into a new experience, and make him feel the responsibility of his position, and you will give him the impulse to learn his new duties and the opportunity to show his real powers. It is because I feel that this sudden entrance into an environment of new responsibility is so necessary that I would regard with suspicion any attempt to provide a gradual transition between school and university methods. In matters of discipline and self-control it is possible and advisable to place responsibility upon school children; in intellectual matters it is not advisable, except for the

Digitized by Google

few who are matured beyond their years. It is, therefore, all the more necessary that this should be done at the moment when they enter the university.

The spirit of independent inquiry which should dominate all university teaching and learning is not to be measured by the number of memoirs published, but it is to be tested by the extent to which university students are engaged upon work for which they feel a responsibility. Visit the universities at the present moment, and, in spite of all the admirable investigation which is being carried on, you will find the majority of students engaged in exercises in which they feel no responsibility whatever. In my opinion this indicates that for them the spirit of true university education has never been awakened. It is, after all, very largely a question of attitude of mind. Any subject of study, whether it be a scientific experiment or an historical event, or the significance of a text, is a matter of interpretation, and to approach it in the university spirit is to approach it with the question, "Is this the right interpretation?" Upon that question can be hung a whole philosophy of the subject, and from it can proceed a whole series of investigations; it embodies the true spirit of research and it opens the door to true learning.

In discussing university education I have not, of course, forgotten that many persons have taught themselves up to a university standard entirely without the aid of professors; indeed, the University of London long ago provided an avenue to a university degree which has been successfully followed by many such persons with the best possible results. But I have endeavoured to remind you that at the university, as at school, for most students the personal influence of the teacher is the important thing; that at the university, as at school, success in teaching depends mainly on the extent to which the interest of the student is aroused; and that at the university this is only to be done by providing him with a purpose and a responsibility in his work in order that he may understand to what conclusions it is leading him. Until this is done we shall still have university students complaining that they do not see the object of what they are learning or understand what it all means. In the hope that the attention of university teachers may be turned more fully to this aspect of their work I have ventured to make it the subject of my address.

COMPARATIVE LIFE TESTS ON GLOW LAMPS.*

BY C. C. PATERSON AND E. H. RAYNER.

Summary.—Comparative life tests of lamps were carried out by the authors at the National Physical Laboratory in conjunction with the New York Electrical Testing Laboratories to see how close an agreement would be obtained by different laboratories. The tests were made on 12 British and 12 American lamps, half of each being tested at each laboratory. The tests indicate that such measurements can be carried out on the basis of the Engineering Standards Committee's specification within an accuracy of ±5 per cent. for carbon lamps.

Object of Tests.—The tests described below were undertaken in order to determine the agreement which it is possible to obtain when life tests are carried out on glow lamps by different laboratories. The useful life of the carbon filament glow lamp is so sensitive to variations in the test conditions, and so many different measurements have to be made in the determination of useful life, that some scepticism is often felt in the accuracy which is possible with this class of work.

Conditions of Test.—The useful life of a lamp is taken to be the number of hours that a lamp will run before the candle-power falls below 80 per cent. of its initial value, the voltage at which it is run being that at which it consumes initially a definite number of watts per candle.* Each lamp, therefore, must be run on the racks at a voltage which, initially, for that lamp, corresponds with the standard value of watts per candle for which it is desired to determine the useful life. Now, the watts per candle of a carbon lamp are inversely proportional to about the cube of the volts, and the useful life of a lamp is inversely proportional to about the sixth power of the watts per candle and to the 20th power of the volts. It will thus be seen that to obtain an accuracy of about 2 per cent. in the useful life requires an accuracy of 0·3 per cent. in the initial determination of candle-power and watts and of 0·1 per cent. in the setting and maintenance of the average voltage on the test racks. Further, the average voltage on life test must be maintained free from fluctuations within very narrow limits (+or−½ per cent.), and the periodical measurements of candle-power must be made to the highest possible accuracy, since the termination of the test depends solely on this. The only indeterminate factor in these measurements is the difference which exists between individual lamps of a batch, and this makes it desirable to take the average of a number of lamps in order, as far as possible, to eliminate this element of uncertainty.

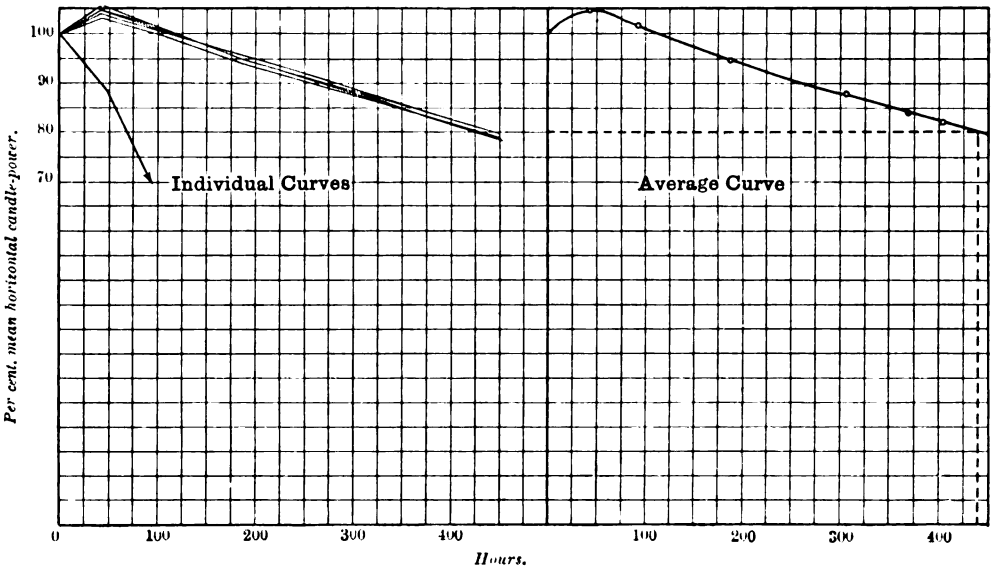

FIG. 1.—LIFE TESTS OF A BATCH OF SIX AMERICAN LAMPS RUN AT 3·1 WATTS PER CANDLE AT THE NATIONAL PHYSICAL LABORATORY.

Candle-power dropped to 80 per cent. after 440 hours. No. of filaments which broke on test—1. (Not included in average.)

The Electrical Testing Laboratories of New York have had a very long experience in the testing of large quantities of lamps for useful life, and it was agreed between this laboratory and the National Physical Laboratory to make a comparative test with a view to finding the order of agreement obtainable under the ordinary laboratory conditions of running life tests. For the purposes of the investigation it was agreed that the New York Laboratory on the one hand should prepare 12 American lamps for running at 3·1 watts per candle and that the National Physical Laboratory on the other should prepare 12 British lamps to run under the same conditions.

At the time of the test the candle-power unit in the United States had not been adjusted in conformity with the international agreement subsequently entered into by the National Laboratories of Great Britain, France and the United States, and there was also a small known difference in the standards of voltage in the two countries. Allowance was made for both of these factors in the determination of the correct voltage for each lamp which was required to give the desired watts per candle. Six of the British lamps were retained for running at the National Physical Laboratory and the other six were sent to New York to be run at the voltage assigned to them in London. Similarly six of the American lamps were

sent over to be run here and six were retained for running in New York.

Initial Tests.—The six lamps sent to London had assigned to them the voltages which gave the values of watts per candle scheduled in Column 1 of the table below. Column II. gives the National Physical Laboratory values for watts per candle of the same lamps. Column III. gives the National Physical Laboratory values for six of the British lamps sent to America, and Column IV. the American values for the same lamps. These figures have been corrected (as stated) for the ascertained difference of candle-power between the two laboratories.

An inspection of these tables shows an average difference in one comparison (Columns I. and II.) of 0·3 per cent., and in the other (Columns III. and IV.) of 0·5 per cent. between the average values of watts per candle assigned by the two laboratories to the two batches of lamps. This discrepancy represents a difference of between 1 per cent. and 2 per cent. in useful life. The greater difference between columns III. and IV. is accounted for by the second lamp, which evidently underwent a change between the time it was tested in London and the measurements in New York. If it had not been for this, the mean difference would have been 0·2 per cent., representing less than 1 per cent. in useful life. The foregoing tests show the accuracy obtainable in assigning the correct voltage at which lamps are to be run on life test at a given watts per candle.

Life Test.—The life test on each lamp was run at the voltage which had been assigned to it by the laboratory where it was prepared. It is, therefore, among other things, a test of the degree to which the voltage measuring and regulating devices, &c., installed for life tests in the two laboratories, give the same results.*

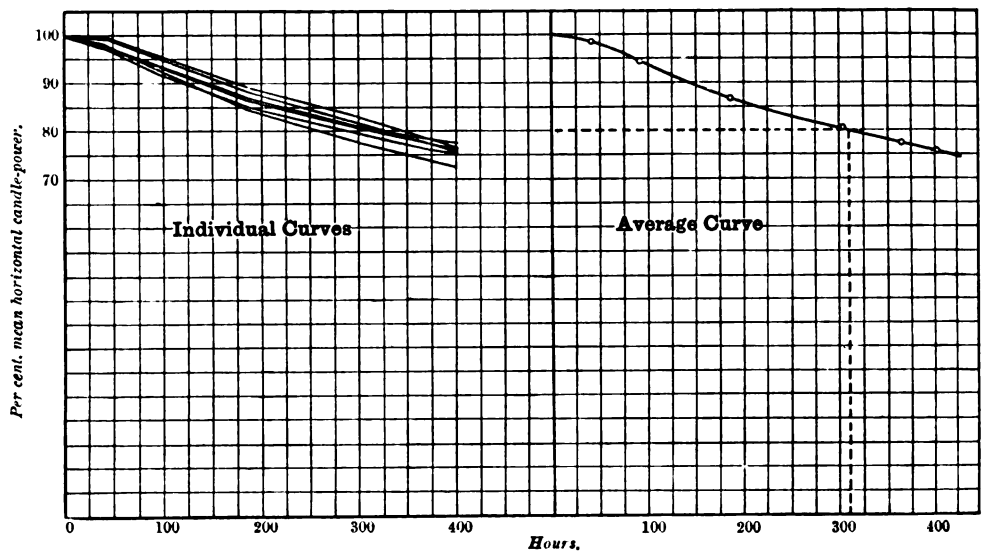

Fig. 3.—Life Tests of a batch of Six British Lamps run at 3·1 watts per candle at the National Physical Laboratory.

Candle-power dropped to 80 per cent. after 310 hours.

The above table gives the average initial watts per candle assigned to the four batches of lamps by the two laboratories respectively.

It will be noted that the batch of American lamps which was run in London has 0·3 per cent. lower efficiency than the corresponding batch run in New York. It is therefore to be expected that it will have a useful life which from this cause is 2 per cent. longer. The life curves of these lamps are shown in Figs. 1 to 4. Figs. 1 and 2 are those for the two batches of American lamps and Figs. 3 and 4 show graphically the results found for the two batches of British lamps.

If the testing arrangements and also the corresponding lamps in the two laboratories were identical these pairs of diagrams should show similar results.

Correcting the result of Fig. 2 to allow for the fact that these lamps started at 3·09 watts per candle instead of at 3·10 we have the following values for the useful life determined at London and New York, as computed from the curves of average candle-power.†

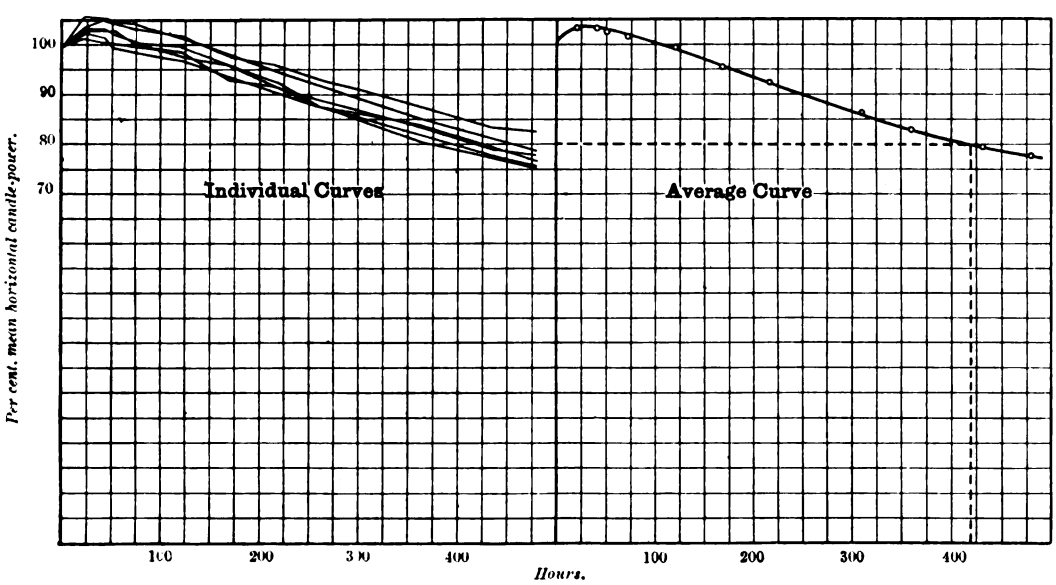

Fig. 2.—Life Tests of a batch of Six American Lamps run at 3·09 watts per candle at the Electrical Testing Laboratories, New York.

Candle-power dropped to 80 per cent. after 420 hours.

* The tests were made with alternating current and a full description of the methods and apparatus at the N.P.L. is given in the "Illuminating Engineer," October, 1908.

† Slightly different values of useful life are obtained, according to whether the computation is made from the curve of average candle-power during life (as in this Paper) or from the mean of the useful lives of the individual lamps in question, which is the usual method at the New York Laboratory. The difference between the two methods is very small and quite negligible in cases where the individual life curves keep well together as in Fig. 1.

Table III.—*Useful Life.*

	National Physical Laboratory. Value.	New York Laboratory. Value.	Difference per cent.
American lamps	435 hours	..... 428	−1·7
British lamps	310 „	..... 330	+6·5
British lamps	310 „	..... 316	+2·0

(with one omitted from average)

The 6·5 per cent. difference is accounted for in the last column by the same lamp (given in column IV. of Table I.), which started at 3·18 watts per candle instead of at 3·10. It is seen clearly (left-hand diagram of Fig. 4) how this lamp increases the average useful life of the batch. If it had not been for this lamp the average useful life would have been 316 instead of 330 hours, thus bringing the agreement between the two laboratories for the British lamps to 2 per cent. instead of 6 per cent.

Conclusions.—In order to obtain quite definite results, free from accidental variations of this nature, it would be necessary to experiment with a much larger number of lamps. Differences between individual lamps of a batch are assumed not to exist, but the assumption is not quite justified where so few lamps are tested.

So far as the tests go, however, they indicate that measurements of the useful life of carbon filament glow lamps can be carried out on the basis of the Engineering Standards Committee's specification to give results which are quite definite and within an accuracy of less than ±5 per cent. when the test reveals that no lamp differs abnormally from the mean. It may be added that, from an experimental point of view, tests on metallic filament lamps should yield a higher accuracy. The tests described here do not form any comparison between British and American lamps as such. The British lamps were all run for about 100 hours before being "prepared" for life test. Hence the unusual form of the early part of the life curves in Figs. 3 and 4 and the apparently shorter life shown by these two figures compared with those representing the American lamps.

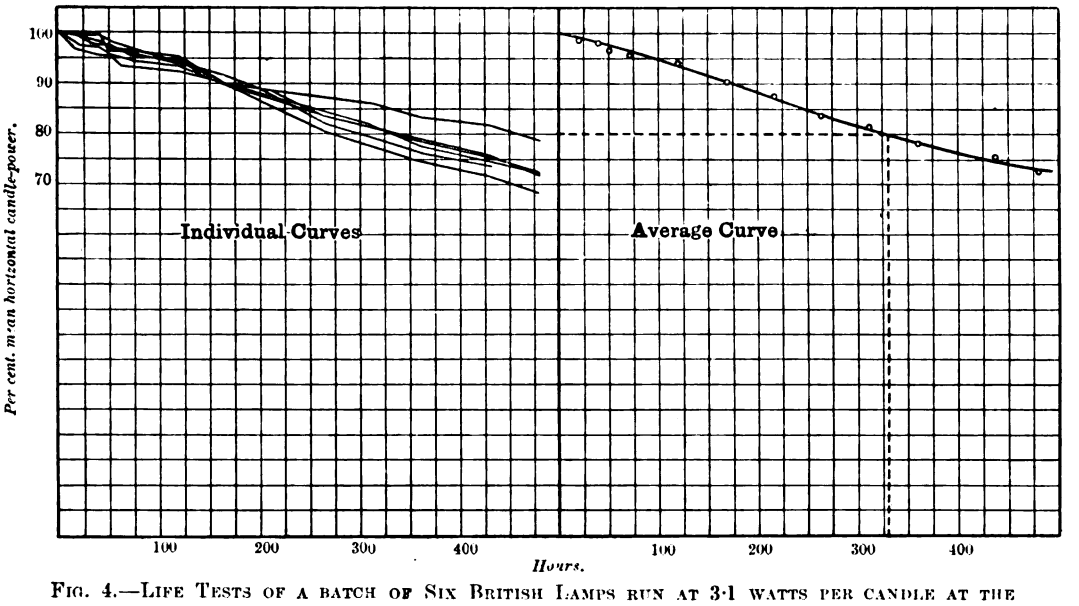

FIG. 4.—LIFE TESTS OF A BATCH OF SIX BRITISH LAMPS RUN AT 3·1 WATTS PER CANDLE AT THE ELECTRICAL TESTING LABORATORIES, NEW YORK.

Candle-power dropped to 80 per cent. after 330 hours.

Paris Floods.—The report of the Commission appointed to investigate the causes of the disastrous floods in Paris at the beginning of this year will shortly be issued. According to "The Times Engineering Supplement" the Commission consider that the generating stations, of which the majority are situated on the banks of the Seine, should be obliged to ensure a sufficient supply of coal and water for their plant; and those stations that are not out of reach of floods should arrange with the others more favourably situated for a supply of current in case of emergency.

THE PRICE OF ELECTRICITY.*

BY EDW. W. COWAN.

Summary.—The author criticises the principles on which the charges for electrical energy are usually based, this basis being an equal rate of profit from every class of consumer. Although this principle is safe, the author argues that best economic results cannot be obtained because the factor of demand is entirely ignored. The demand for electricity is of a "composite" kind, energy being required for light, power and heat. Classified tariffs should be adopted so as to secure the greatest economic advantage. The author supports his views by reference to the adjustment of prices in railway freight charges and other lines of business.

General Principles.—It is, I presume, an obvious truth that the closest and widest possible correspondence between the incidence of supply and the incidence of demand secures the greatest economic advantage to the community; but it is not perhaps so obvious that the closest coincidence of supply and demand is consistent with wide variations in the incidence of the forces which govern supply and demand and their resultant effects. Utility is not necessarily a measure of the effective demand of which it is the cause, and supply may be forthcoming independently of any direct influence of utility, operating through demand.

The forces at work behind the scenes may often operate more effectively for the attainment of the desired end when they are not coincident in respect to time nor correspondent in respect to degree.

This apparent irregularity of operation is illustrated in the case of the market for wheat and straw. The production of straw is independent of the demand for it (excepting through the indirect influence of an increased demand for straw lowering the price of wheat and thereby increasing the supply of wheat and consequently the supply of straw which is definitely related to it).

If the two commodities are treated as one, their joint price will be determined by the resultant effect of the combined supply and the combined demand, but the relation between the prices of the two parts of the supply, that is of the wheat and the straw, is determined quite independently of the relative cost of producing them. The sum of their prices must, of course, at least equal the expenses of production, that is to say the forces which govern the joint supply will exercise direct influence. In regard, however, to the separate prices of the two parts, in respect to their relation to each other, it appears to be practically correct to assume that they are determined entirely by demand† if the best results are to be obtained.

In Fig. 1 the play of these forces is statically indicated in the case of a demand which is in part met by a by-product supply.

It will be noted that at quantity of supply O.M. there is a critical change in the character of the supply curve due to the change from by-product supply to supply produced under normal conditions.

If the conception of joint production be accepted as valid, it explains many discrepancies in the relative prices of joint products in respect to the expenses of their production. Such cases are the prices of soap and its by-product, glycerine (£50 per ton, whereas the cost as a by-product is about £1), the different rates for transport of iron and brass, the Post Office rates for circulars and letters (although the former cost more to carry). The price of a by-product

* Paper (somewhat abbreviated) read before Section F (Economic Science and Statistics) of the British Association at Sheffield.

† It is not overlooked that, strictly speaking, demand alone cannot determine price, but as the influence of supply is practically rigid in the case of a by-product, such supply is not a function of price. The one necessary result is that the whole of the by-product supply offered should be sold at the highest obtainable price and in order to achieve this result, regard to the demand factor only is required in fixing its price. It is the forces behind demand and supply which we have to consider, and as price cannot affect the amount of supply offered, it should be fixed with reference to demand only.

Digitized by Google

is what it will fetch. In such cases the relative cost of production may be ignored in fixing the price. The business should be treated as a whole and not as an assembly of distinct businesses standing alone.

Accepting such a view, we may postulate the following:—

1. When the cost of production of one unit of supply in a business is affected by the cost of production of the other units, no single unit can be said to have a separate cost of production.

2. If, under such conditions, an attempt is made to fix the price of each unit of supply upon the basis of its separate cost of production, loss will result.

3. The loss is due to the relatively faulty correspondence between the incidence of supply and of demand which arises when price is not adjusted, as nearly as supply conditions will allow, to the intensity of demand.

Further, there appears to be no reason, in theory, why any supply should not be treated as a joint supply by dividing it into two or more parts and selling these parts at different prices. But there cannot be two prices in the same market at the same time, and in practice therefore the benefit of this system of price gradation can only be partially realised by selling the same product at different prices at (1) different times, or (2) in different places, or (3) in different forms. The operation of such a system is essentially beneficial because there results a more extended and efficient distribution of wealth than is possible with a fixed price.

The Supply of Electricity.—We have in electricity a commodity which can be put to divers uses. Electricity is in demand for light, heat, power and electrolytic uses primarily. The demand is really

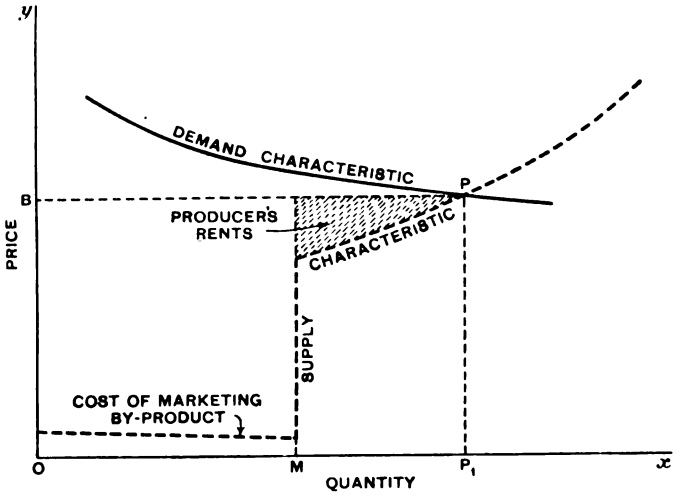

FIG. 1.

for light or heat or power, &c., and the fact that electricity is common to the supply of these commodities is only an incidental fact of no essential economic import.

Clearly the influence of demand upon price will differ considerably in respect to these different commodities. The demand for electricity for light will depend largely upon the alternative forms of light supply and their prices and partly upon its specific utility for that purpose; so with heat and so with power. The demand for these commodities is not a demand for electricity, excepting in an indirect sense.

Regarded in this light, the demand for electricity is a "composite" demand, just as the supply of wheat and straw, of beef and hides, of gas and coke, &c., are "joint" supplies. Further, so far as the different classes of demand for electricity vary in their incidence in respect to time, the supply of electricity may be considered as being "joint" in its character, as the demand for it is composite in its character. Thus, if the demand for power were a day demand and that for light a night demand, the same plant could supply both, and the supply would be correctly classed as a "joint" supply. It will be seen later that electricity supply is partially of a "joint" character. But there is this difference, that the supply of electricity being common to all its uses, one commodity only is sold in the market. We may compare the case to that of selling cattle to two customers, one buying for the sake of the hides and one for the sake of the beef. These two customers could not be charged different prices, because they buy one commodity, viz., the cattle, in one market. Now electricity could not be sold at different prices if it were sold over the counter by the yard or the pound. A point of rather nice distinction arises therefore—is it practicable to sell electricity at different prices for different uses and, if so, is it fair to make any such discrimination? If my argument is correct it will be admitted that there may be an advantage in doing so, an advantage to the producers and an advantage to the consumers, by rendering the supply more flexible, and thereby enabling it to adapt itself more fully to the character of demand. There are two questions at issue: (1) Is there a theoretical advantage in differentially charging consumers upon this basis? and (2) if so, is it practicable and just to apply the system to the sale of electricity?

The answer of electrical engineers to these questions is emphatic; they deny that any advantage can be gained by the system and hold that it is inequitable and inexpedient to employ it.

As evidence of the views held by leading electrical engineers, I give quotations below from various sources.

A definite policy in regard to the question began to take shape in 1892 when Dr. John Hopkinson delivered his Presidential Address before the Junior Engineering Society upon the subject of the cost of electrical supply. In this address it is pointed out that the charge for a service rendered should bear some relation to the cost of rendering it, and a method of charging for electricity supply is suggested which will more nearly secure the observance of that relation than attempting to charge by a uniform rate per unit. Dr. Hopkinson was dealing with the supply of a single commodity, viz., electricity for lighting purposes, and under such circumstances the principles he advocated were both sound and practical.

This was followed in 1896 and 1901 by Papers by Mr. A. Wright in which the principle was laid down that municipalities cannot be justified in selling electricity to one class of their ratepayers at a lower percentage of profit than to another class. He asserts very definitely that unless the price to any consumer covers his proportionate share of the standing charges and of the production charges a real loss must be incurred. This is a view which I find myself unable to accept.

Mr. C. H. Wordingham, in his book on "Central Station Practice," states that it is illogical to make the rate of charge depend upon the class of supply. In 1907 Mr. J. F. C. Snell read a Paper before the Institution of Electrical Engineers, in which he emphatically contended that the only rational basis of charging was one which was strictly the cost basis. Mr. J. H. Rider supported this view. Having regard to commercial stability, in his opinion the only true basis on which to charge is the load-factor basis tempered by diversity factor.

This latter statement cannot be disputed, and if stability is the chief end in view and not the rendering of the largest possible service to the community, the system of charging strictly according to cost would be an unassailable system. But, as in most undertakings, the attempt to reduce business to a process of mechanically grinding out equal percentages of profit upon all operations renders the obtaining of the maximum aggregate profit to producers and consumers impossible. Some stability must be sacrificed in order to reach the higher planes of successful undertaking. There is admittedly a risk in endeavouring to forecast the course of demand and in establishing vested interests adapted to that estimate, but there is in such an operation a large aggregate gain even though that gain is accompanied by occasional losses. A business is not and cannot be made wholly a machine, it is more akin to an organism, and as such must develop powers of adaptation to varying conditions which are beyond the range of the function of mere mechanism.

In 1908 Messrs. Handcock and Dykes read a Paper before the Institution of Electrical Engineers in which they contended that differentiating in the charges to consumers according to the class of their demand was illogical and illegal. On the other hand, Mr. S. L. Pearce goes so far as to favour the idea that new power consumers should benefit to some extent from the smaller capital charges of new plant necessary for their supply.

The quotations I have given make quite clear the attitude of the industry towards this question. It is a quite logical attitude, and if we accept the premises upon which it is founded, viz., that the supply of electricity is the supply of one commodity and can only legitimately be considered in that light, no criticism can be made which is not applicable to the supply of any other commodity at a price having a fixed relation to cost. It is impossible to escape from the conclusion, however, that electrical engineers have accepted the popular belief that the selling of all commodities at prices strictly based upon cost is not only commercially expedient but is morally right. They always speak of lower charges in relation to cost of some consumers as involving injustice because, according to their conception of the operation, the lower charges to some must be balanced by correspondingly higher charges to others. To quote a common expression, "some consumers are penalised in order that others may be subsidised."

There does not appear to me to be any validity in this view regarded as a principle which should govern electricity supply

Digitized by Google

tariffs. With a scientifically adjusted scale of charges, having due regard to the market price of each class of commodity supplied, whether light, power, heat, &c., it is possible in many cases, not only to confer benefits upon the power and heat users, but to supply the light user at a lower price than would be possible if the principle of a uniform rate of profit from each class of consumer were adopted. The percentage contribution towards the standing charges of the business by the power and heat users may not be so large as the contribution of the light consumers, but it is a contribution, and as such provides a fund which is applicable to the reduction of prices to the light consumer, who may thus obtain his supply at a rate lower than would be possible if power and heat consumers were refused supply at prices which they could afford to pay, that is to say, prices which competed with the market price of power or of heat obtained by alternative methods.

The criticism of this Paper is directed against the acceptance of the principle that commercial expediency and moral justice are attained by fixing price upon the basis of equal profit from all classes of consumer. But I desire to emphasise that it is not intended to make out a case against the practice of the industry. This would require an elaborate investigation, in view of the many factors which influence the establishment of a practical system of charging. It is not that I hold that the practice of the electrical industry in this respect is right, but it seems to me to be worth while to attend to the question of sound principle in the first instance, leaving the application of it to actual tariffs to form the subject matter of another investigation.

If we recognise that the cost of each unit of electricity supply is affected by the total number of units supplied, we must admit that no separate unit can be said to have a separate calculable cost. Once this organic relation of the parts of a whole business is accepted, a system of attempting to price every part of a supply according to the cost of producing it, is seen to be scientifically faulty, though the exigencies of other conditions may compel us temporarily to ignore the truth of that fact. The rigid line of a fixed price for a given objective service has many uses and conveniencies from the book-keeping point of view, and is attractive on account of the security which follows its adoption. But the possible aggregate dividend is less under a fixed price than under a graded. If we regard the function of price as being a purely distributive one, it is not difficult to realise that a more efficient distribution will be effected if price can take upon itself a flexibility which reflects the variations in the intensity of demand. Demand must continue to vary in character and in degree as between its parts, and a rigid adherence to a system of pricing which only regards demand in the lump may involve the sacrifice of wealth which might be realised by the attainment of a closer adjustment of demand's detailed incidence in relation to supply. If we ignore the character of demand we can only succeed in satisfying a smaller measure of it. Demand should be the predominating influence, as it is the cause of value, supply is the servant of demand, and producers must seek to adapt supply to demand and not try and force demand to adapt itself to supply.

We have only to investigate the effect of treating the extreme cases of joint supply, such as wheat and straw, or beef and hides, mutton and wool, &c., &c., as if they were single supplies, and the great economic loss which must accompany such a practice will become at once apparent. The aggregate supply must be less and both producers and consumers must suffer loss.

Apart from the economy of production upon a relatively large scale there is a specific economy in combining separate businesses into one business, such as the supply of electricity for light and for power, &c. The differences in the character of the demands allowing of a common use of some of the employed capital and other elements which form a part of the expenses of production. This diversity of incidence of the respective maximum demands may be a source of considerable economy in the utilisation of capital which would otherwise be inert during a greater part of the 24 hours.

These two economies appertaining to combination, provide a fund which may be applied to the increase of profit or to the reduction of price, or to both.

In the case of a municipality where increase of profit is not desired the undertakers have to decide how to apply the gain, and they, quite logically, apply the gain due to production upon a large scale equally as between all classes of consumers, and the gain due to diversity of maximum load, they aim at applying to the reduction of price to those consumers whose maximum load diverges in respect to time from the aggregate maximum load demanded from supply works. As the incidence of the maximum loads of consumers in relation to the maximum load of the supply works is difficult to ascertain, a rough approximation is often made by reducing the price to the class of consumers, say, power users, whose mean maximum demand is estimated to diverge from the maximum of the whole demand. It is sound policy to do this because relatively profitable customers are encouraged, and to encourage such customers is legitimate and right from every point of view.

But it surely cannot be held that the divergent consumer has any sort of moral title to this benefit? A part of all supplies, whether of grain, coal or manufacturers, costs less to produce than other parts and for similar reasons. The purchaser does not claim discriminative treatment on such grounds, he does not consider that he has any moral right to benefit according to the relative cost of the part of supply he buys compared with the cost of the parts bought by other consumers. So with electricity supply. That A should have any moral claim to a reduction in price because his maximum demand does not coincide with B's plus C's is a quite untenable conclusion, unless, of course, he undertakes that his maximum demand shall in this respect diverge from theirs. He must do something to give him any moral basis to a claim. If the maximum load of one class of consumer exceeds that of another class there is no principle of equity which requires that the benefit of the divergence of their maximum demands should be given to the class with the lower maximum demand. A day demand may exceed that of a night demand and yet the day demand be credited with the advantage of by-product use of the plant, and not the smaller night load, without any infringement of equitable principle.

I have dealt with this point at some length because I am anxious to establish the principle that the undertaker, though he is administering a monopolistic business, is, from the point of view of equity, free to apply the gains due to combination as may be best for the business as a whole.

(To be concluded.)

RECENT PATENTS IN WIRELESS TELEGRAPHY.*

BY W. H. ECCLES, D.SC.

(Concluded from page 849.)

An ingenious combination of wireless telegraphy and the method of the submarine bell appears in No. 10,083 (1909). It is due to J. Schiessler, and its purpose is to obtain a measurement of the distance of a ship or other station emitting both kinds of signals simultaneously. The principle employed is the simple one of measuring at the receiving station the time interval between the arrival of the Hertzian wave and of the sound wave. The suggested receiving apparatus comprises five circuits—a circuit containing a submerged microphone, a telephone relay circuit, the circuit of an electrical chronometer, a circuit comprising an electromagnet that sets a tuning fork in vibration, and the telephone circuit of a wireless receiving installation. This recital gives a sufficient insight into the mode of operation of the apparatus, and conveys an adequate notion of the complexity of the scheme. If the difficulties inherent in respect of time-lags in the wireless apparatus can be overcome, and if the other parts of the apparatus can be so developed as to be installed and worked at even a shore station, the thing would be a great boon to navigators.

Here we may mention R. A. Fessenden's description, in No. 17,450 (1909), of a form of sending or receiving antennæ which consists of two capacity areas, one of which must be insulated. Fig. 9 is the diagram accompanying the specification; its complexity and novelty are only apparent. The inner web of wires is shown in two portions or may be connected by switch 11, but is always insulated, is tuned by the lengthening coil 12 and is charged by the high-frequency dynamo 5 through the sending key 25. The outer web of wires may be insulated, and then constitutes a balancing capacity, or may be earthed by switch 10, when it is given the name "wave-chute"; it is connected by coils 21 and leads 8 to the other terminal of the oscillation generator 5. Switch 26 substitutes receiver 27 for the dynamo, when receiving. The numerous leads 8 are, of course, very necessary when so extended a web of wires is used as in this balancing capacity. The wire networks may be supported on poles only 20 ft. high, and this reduction of the height of the aerial is put forward as the advantage of the proposal. The whole matter is summed up in claim 1 of the specification, where the emphasis

* Copyright. All rights reserved.

Digitized by Google

falls on the sentence: "an antennæ . . . elevated to a height above the ground considerably less than its largest horizontal dimensions and a wave-chute consisting of a plurality of conductors of very low resistance . . . beneath the horizontal capacity."

Another patent relating to antennæ is that of C. Bordeloni, No. 24,187 (1909). A new disposition is given to the aerial conductor at a receiving station with the object of attaining accurate syntony with even strongly damped waves, as well as freedom from atmospheric disturbances. This is stated to be achieved by causing the whole length of the aerial to act upon the secondary circuit. It is the part of the aerial outside the instrument room, as well as the aerial lengthening coils inside, which is made to act upon the secondary. This is accomplished by extending the secondary by wires running outside the station alongside the aerial. In both of the sketches appearing in the specification (not reproduced here) the aerial is a loop aerial, and there are two secondary extensions. The extensions are each a number of vertical straight wires, and are each coupled to one side of the looped aerial; and both are, besides, coupled with the aerial inductance coils. The whole arrangement may thus be regarded as a closed or nearly closed circuit aerial with a single open secondary circuit folded along it and

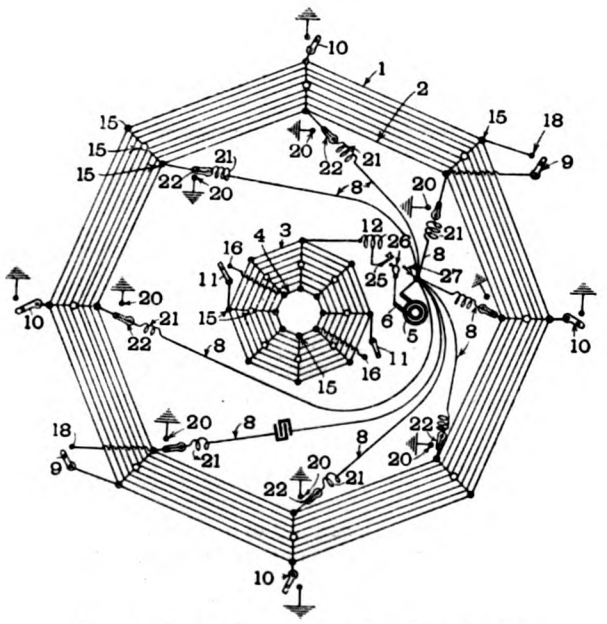

Fig. 9.—R. A. Fessenden, No. 17,450 (1909).

coupled to it as stated. The advantages of this are discussed by the patentee, but closer reasoning, not to mention practical demonstration, is needed.

Patent No. 13,865 (1908), taken out by R. A. Fessenden, is an application for protection of plant for producing and receiving singing signals of rather high acoustic frequency, on the ground of having discovered that high-pitched signals are more easily distinguished from atmospheric disturbances than those of low pitch are. A frequency of 900 per second is suggested as being good, and is said to give the operator much greater ease in reading through atmospherics than does a frequency of 250 per second. A method of carrying out telegraphy with such a frequency is described and consists of obvious means of running and regulating an alternator of 900 cycles, of producing electric waves, and of receiving the signals.

Marconi's Wireless Telegraph Co. and H. J. Round, in No. 11,544 (1909), set forth a means of determining the azimuth of a sending station and of sending waves mainly in a specified variable direction. Put concisely, the method, as adapted for receiving, consists in comparing the loudness of the signals received by two directive aerials; the receiving apparatus being switched from one aerial to the other rapidly for this purpose. Within certain angular limits the method will probably prove to be the most accurate yet proposed. Its application to reception seems more immediately useful than its application to transmission, and, therefore we need speak here of reception only. In Fig. 10, let OD^1 and OD^2 represent in plan the directions in which two fixed directive aerials would radiate and absorb most powerfully. The polar diagrams of two such aerials equally energised are shown by the curves C_1 and C_2. A radius vector drawn in any direction in these curves may be taken to represent the capability of the aerials for absorbing energy from that direction. Plainly there is at least one direction from which waves might come and produce signals of equal intensity in both aerials, namely, the direction OB′. The form of the absorption curves at this point shows that if the distant sending station moves even slightly off the line OB′ the strengths of the signals become very different on the two aerials. The specification goes on to describe how the direction of equal intensity can be changed from the line of bisection of the angle between the aerials. Suppose, for example, the signals of aerial OD^2, and that alone, are weakened from OC^2 to OC^3 by aid of a device inside the receiving station; then the direction of equality of signals will lie along the new direction OB^2. A sending station along the direction OB^2 may thus have its bearings determined, though with less accuracy than would be the case with a station along the direction OB′. *Mutatis mutandis*, what has been said of reception applies to transmission also. Means of carrying out the weakening of the signals on either aerial are suggested in Figs. 11 and 12. Here a^1 and a^2 are two directive aerials placed at an angle, s a switch, r a sending or receiving apparatus, E the earth connection, o, i^1, i^2, j^1 j^2, inductance coils, and d a rheostat. The switch s is made to move quickly to and fro, so that signals are got alternately from the two aerials and comparison easily made as to loudness. In Fig. 10 alteration of the intensity is effected by moving coil i so as to alter the coupling with i^1 and i^2. It may be remarked that if the circuit ri is intended to be a tuned circuit, this mode of working is utterly bad; the alteration of the coupling must produce mistuning and consequent con-

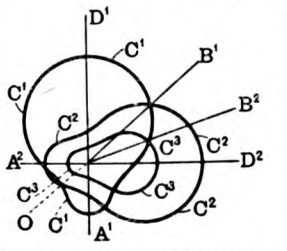

Fig. 10.—Marconi's W. T. Co. and H. J. Round, No. 11,544 (1909).

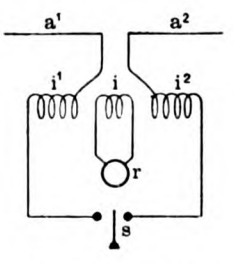

Fig. 11.—Marconi's W. T. Co. and H. J. Round, No. 11,544 (1909).

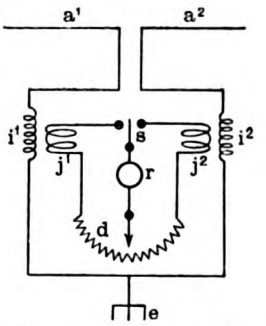

Fig. 12.—Marconi's W. T. Co. and H. J. Round, No. 11,544 (1909).

fusion. In Fig. 12 the coupling to either aerial is kept fixed in amount, and either aerial is lowered in efficiency by varying the rheostat. Taken as a whole, the invention is an important one because it overcomes a difficulty that blocks the progress of all previous methods—the difficulty, that is, of determining exactly the direction of maximum loudness on a blunt-nosed polar curve. If the present method can be improved so as to leave no room for ambiguity between fore and aft and beam bearings (as no doubt it can) it should be of immediate and immense value to the mariner.

There is very little to chronicle in respect of receiving apparatus and detectors. G. Marconi and Marconi's Wireless Telegraph Co. describe an adaptation of Dr. Fleming's valve to an old suggestion for arranging a pair of detectors to enhance the selectiveness of a receiver. Each valve is placed in a vibrative circuit, one circuit being in perfect tune with the

Digitized by Google

signals to be read, the other being slightly out of tune. The supposition is that if the valves be arranged to oppose one another in the telephone circuit, undesired signals, if of wavelength reasonably distinct from those of the two circuits, will annul themselves by affecting both circuits almost equally. The signals to be read affect one circuit and its detector much more than the other, of course. So far as the cutting out of signals is concerned, the whole device seems to be a roundabout way of doing what can be done just as well by using a very loose coupling and very sharp tuning; but for cutting out atmospheric disturbances the method is very valuable so long as the two detectors remain equal in every respect. In No. 6,008 (1909) R. A. Fessenden proposes to construct a recording detector of oscillations by aid of the frictional method of measuring changes of magnetic induction. The frictional method of estimating the variable magnetic flux across the surface of contact of two pieces of iron consists of measuring the varying tangential effort necessary to make one body slide over the other, and was applied by W. H. F. Murdoch several years ago to making commercial tests of iron under ordinary ranges of change of B and H. The proposal in the present patent is to detect in this way the extremely minute changes produced in the magnetic flux by the weak electrical vibrations received on an air-wire. Finally, in No. 10,772 (1909), G. W. Pickard, dealing with contact detectors, emphasises strongly the necessity of provision of very accurate mechanical adjustment of the sensitive parts. The specification claims the use of an iron-pyrites and brass contact, together with a frame comprising a slow screw motion for the making and keeping of a contact of definite pressure at an invariable point of the crystal. Iron-pyrites is stated to be very sensitive and yet capable of taking heavy electrical discharges without injury.

In wireless telephony there is no striking progress to discuss, but there are a few specifications of minor importance published. In No. 7,906 (1909) W. Burstyn revives with a slight modification the old proposal to conduct wireless telephony by causing the speech sounds to vary the capacity of a condenser associated with the aerial radiator. The variation is to be accomplished, as usual, by making the condenser a part of an electrostatic telephone whose moving plate has its motion dictated by the voice. The novelty of the patent appears in employing an ordinary current-carrying microphone, which is itself actuated by the voice, to produce "electrostatically" the motions of the diaphragm of the electrostatic telephone. In No. 16,183 (1908) J. Schiessler describes a telephonic relay based on the well-known principle of bringing a fluctuating microphone-current into such relation with an unstable resistance (*e.g.*, a vibrative arc) that great fluctuations shall be produced in the currents through the resistance. Finally, in specification No. 2,330 (1909) F. J. Chambers describes a method of applying a manometric flame to the problem of varying in accordance with speech sounds the electrical magnitudes in a vibrative circuit. The flame, which is here regarded as an electrical conductor, is projected horizontally between a pair of converging electrodes so as to complete the circuit to a greater or less extent according as the flame is longer or shorter —the changes of length of the flame being dictated, of course, on the ordinary manometric principle, by the sound-vibrations.

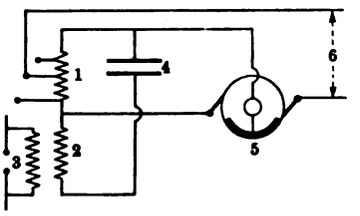
A NEW METHOD FOR PRODUCING HIGH-TENSION DISCHARGES.*

BY PROF. ERNEST WILSON AND W. H. WILSON.

It is hardly necessary to mention the importance of high-tension electric discharge apparatus at the present time, and therefore improvement in the direction of increased reliability and portability, decreased cost, and increased efficiency is highly desirable. Now that lighting systems—alternating or direct current—are generally available the advantage to the medical man will be great if by the insertion of a wall plug he can readily secure very sharp fluorescent screen effects. In radio-telegraphy the importance of improvement in the directions named cannot be over-estimated. The extended use of the apparatus on board ship makes it very desirable that it should be reliable, and in the field for military purposes great lightness and portability are desired. Other directions in which cheap portable sets will make for progress are in connection with the forcing of the growth of plants, and fog dispersion.

Referring to the diagram of connections, energy is (according to this method) stored in a magnetic field by an inductance, 1. It is then permitted to surge into a condenser 4, which forms with the inductance 1 a low-frequency oscillatory circuit. When the energy is accumulated in the condenser 4, the latter is mechanically bridged across the primary winding 2 of an induction coil with which it forms a high-frequency oscillatory circuit. The energy is then transmitted by the secondary winding 3 of the induction coil to the work circuit, and can be of an oscillatory or uni-directional character, according to the purpose in view. The above cycle of events is controlled by a contact maker, 5, which is driven by a small motor arranged with commutator and slip-rings so that the apparatus can be worked when the supply mains 6 are either direct or alternating current. Tapping points on the inductance 1 allow of a suitable range of voltages being used.

Going a little further into detail one may say that at "make" the system is switched on to the supply mains, the current rises in the winding of the inductance 1, and builds up the magnetic field. When sufficient energy has been stored the system is severed from the mains, and this may be referred to as the epoch of "break." As only the current in the condenser 4 passes through the primary winding 2 the inverse E.M.F. induced in the secondary winding 3 is so small as to be negligible, but if desired it can be entirely eliminated by a modification in the connections. At the epoch of "break" the energy stored in the condenser 4 is added to that in the inductance 1, and then the total energy in the inductance 1 begins to surge into the condenser. At the precise epoch when the condenser has received the whole of the energy in virtue of its reverse charge, the contact maker 5 short-circuits the inductance 1. The condenser then discharges with great rapidity through the



primary winding 2, and the energy then oscillates between the condenser and primary winding in well-known manner. As is also well known, the E.M.F. induced in the secondary winding 3 may be of an oscillatory or uni-directional character according to the nature of the work circuit.

Briefly the following are some of the advantages gained:

1. For X-ray work the inverse E.M.F. is eliminated, thereby leading to increased life of the tube and to a more sharply defined radiograph.

2. Only a small magnetising current is required, as the inductance 1 has nearly a closed magnetic circuit. This gives rise to very small C^2R loss and consequently higher efficiency.

3. On account of the long periodic time of the system, the voltage across the contact of the interrupter 5 at "break" does not rise to a high value, or rises so slowly that the contacts are well separated before it is developed. No oil or coal gas is required.

4. The method lends itself to few secondary turns and this keeps down the time constant. It also makes the coil lighter, cheaper, and more compact.

5. The method lends itself to low secondary resistance—a point of great importance in wireless telegraphy.

6. The iron in the spark coil can be kept small in amount, and special attention can be paid to its lamination and insulation, as it may have to be operated at frequencies of some thousand per second.

7. The elimination of sparking increases efficiency, and on board ship, where coal gas is not conveniently obtained, this is an advantage.

8. The apparatus is light, portable, reliable and cheap.

9. The apparatus can be worked from direct-current or alternating-current systems at usual voltages, or from a portable battery of a few storage cells.

10. The oscillating current at "break" does not pass through the battery and hence does not assist in its discharge.

11. The iron in the magnetic circuit of the external inductance 1 has only to operate at low frequency, and hence it has not to be finely laminated.

TRANSMISSION INSULATORS.*

BY A. S. WATTS.

Summary.—The author describes the development of the high-tension insulator in America and in Europe, and compares the designs which have been evolved in the two continents. Finally, he suggests a light type of insulator which he considers is particularly suitable for pressures of from 60,000 to 100,000 volts. It is formed from a porcelain tube with undercut corrugations.

That a thoroughly practical and successful transmission insulator is not as yet on the market is yearly, almost monthly, evidenced by the attempts on the part of engineers to produce a new and superior insulator design or combination. All such designs are of interest to the insulator-producing and using world, since it can only hope thus ultimately to reach perfection. If the development of high-tension insulators, however, is to continue, as in the past, in the hands of the electrical transmission engineer it seems highly important that he possess some reliable comparable data upon the relative values of the various insulators now in use, in order, not only to be able to select from those now available, but also to place an intelligent value upon any new design presented for his approval. At the present time such data is so meagre that it is practically worthless. American engineers may justly feel proud of the progress made in the U.S.A. in the development of insulators for high pressures, compared with the progress made in Europe in this line.

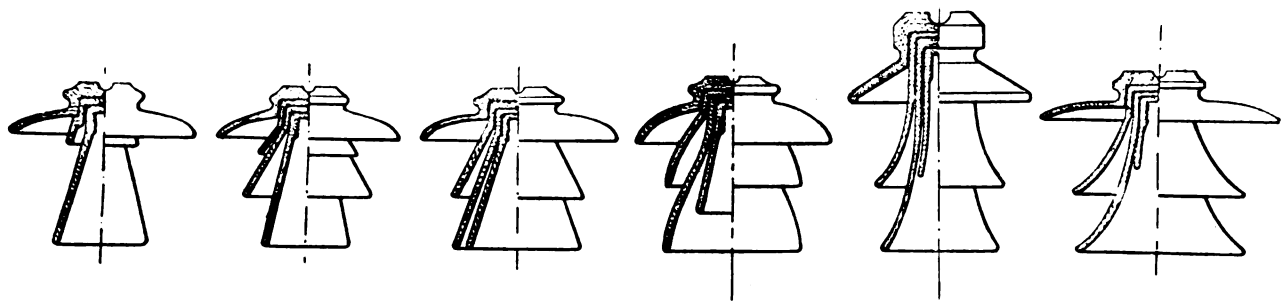
American Insulators.—The author first considers the development of insulators in the United States. In order to facilitate comparison, the illustrations of insulators are reproduced to the same scale. Scarcely 10 years ago the first genuine high-tension insulator was produced. Its construction was similar to the type shown in Fig. 1. This insulator consisted of a porcelain head and intermediate shell manufactured separately and fused together during the burning process by means of a layer of glaze. With these was used a glass centre which was attached to the other parts by means of Portland cement. This insulator was a great advance over the simple bell insulator, which had been used up to this time and which was still in service in Europe. The next step in insulator development was the lengthening of the intermediate shell and the introduction of a narrow flange on the under side of the top shell in order to lengthen the bearing surface between the top and second shells, which were now united by Portland cement, as the glaze joint proved unreliable when subjected to great strains or sudden changes of temperature. The centre was also now made of porcelain, thus eliminating the use of the glass, which caused trouble on account of its brittleness. The next step was the extending of the head portion sufficiently to permit of the introduction of a fourth shell. This type is illustrated in Fig. 2.

Up to this time the development of the insulator consisted merely in the expansion of the original type, thus furnishing greater striking and leakage distances. Insulators like that shown in Fig. 2 proved very successful from the point of manufacture and also for employment on transmission lines up to 60,000 volts, provided the operating conditions were good. If the conditions were severe or an addition of 6,000 volts was considered, the mere increase of dimensions failed to give satisfactory results.

A series of insulators varying considerably in form and possessing properties peculiar to themselves resulted. In this class are the insulators illustrated in Figs. 3, 4, 5 and 6. The insulator shown in Fig. 3 was designed with the idea that, by having two large shells close together, one would obtain two surfaces to which the rain could not gain access. The result, however, was that insects and dust collected in this protected place where the wind could not dislodge them, and this proved a conductor equal to the film of moisture accumulating during a storm. The proper cleaning of such an insulator also proved very difficult because of the narrow opening. Difficulties in manufacture were also experienced. Fig. 4 represents an insulator of almost the same dimensions as that in Fig. 3, but much superior both as regards operating efficiency and success of manufacture. This type has the peculiarity of having only convex surfaces exposed to the weather. This insulator was never put into service in the United States, although many thousands were made and sent to Japan, where they proved very successful. Fig. 5 represents an elongated specimen of the type shown in Fig. 2, and had previously been extensively employed for 45,000-volt lines. This insulator was manufactured and employed only as a three-part insulator, the pin being cemented directly to the longest shell, which served also as centre. Its failure when employed for high voltages lay in the fact that when put to the strain which its size seemed to warrant, it proved unequally balanced, causing the centre to puncture during the stress of storm service. This difficulty was overcome by expanding the various dimensions sufficiently to permit of the introduction of a fourth shell, as here shown, thus placing two thicknesses of porcelain between the steel supporting pin and the first exposed surface. However, when thus redesigned, this type proved so heavy and so expensive to produce that it was never put into use.

In Fig. 6 is shown the Fig. 2 type expanded instead of elongated. This type proved very successful for voltages up to 75,000, but, like Fig. 5, the cost of production and the expense of installing such heavy insulators is in most cases not justified by the additional efficiency obtained. In the manufacture of such an enormous extending head as this insulator possesses much difficulty was naturally experienced on account of warping during the firing process.

In the United States, as in Europe, the underhanging insulator came as a result of the discovery that for proposed 100,000-volt lines no pin-type insulator could be successfully employed. In the design of an underhung insulator it is generally agreed that it must be so constructed that in case the insulator is destroyed the line will not drop. Of the insulators so constructed, the best known types are the Hewlett insulator (Fig. 7) and the Duncan insulator (Fig. 8). In the type illustrated in Fig. 7 the supporting cable passes into the porcelain, below and through the loop which supports the next lower insulator or the transmission line. Thus there are two intersecting loops which certainly furnish absolute security against the dropping of the line. On the other hand, there is an opening in the top of the insulator into which water may enter and render the insulator liable to burst by frost unless the curved hole is so bored that it tapers from each opening to the middle. Of the type illustrated in Fig. 8 the author's personal observation in connection with the manufacture of many thousands has convinced him that with the porcelain under compression, as it is here, it is impossible to pull the bolt out of the cap with any amount of load which could be introduced by means of snow or ice added to the cable. In fact, the cable would itself part long before the strain on the insulator became enough to cause rupture. The Swedish engineer, Olav Ingeborg, who is transmitting 200 H.P. at 500,000 volts for use in his research laboratories, has recently equipped his line with this type of insulator exclusively, after testing practically all types.



FIGS. 1 TO 6.—CHRONOLOGICAL DEVELOPMENT OF AMERICAN HIGH-TENSION INSULATORS.

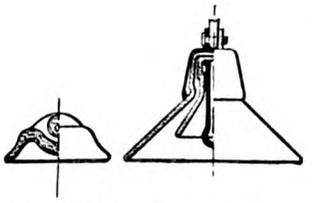
European Insulators.—The development of transmission insulators in Europe has been along very different lines, although the original type employed was very like that first used for lower voltages in the United States. While in Europe much larger single pieces of porcelain are produced than in the United States, the demand for transmission insulators for voltages above 50,000 has been comparatively small, only three lines operating at pressures higher than 50,000 volts. Regarding insulator development in Europe, the Hermsdorf Porzellanfabrik patented in 1897 the "delta glocke" insulator (Fig. 9). This type of insulator has been produced in all sizes up to about 12 in. diameter, and throughout Europe is

* Abstract from the "Electrical World."

Digitized by Google

undoubtedly the most extensively employed type for moderate voltages. It has the peculiarity of having only one thickness of porcelain between the line and the pin. In the manufacture of insulators in the United States this has been considered unreliable. Furthermore, with American materials, the production of large single piece insulators has not been successful. In Germany such insulators are produced by two different methods. One is to form a mass of body large enough to permit the bells to be turned out of the mass on a lathe while still in the half-plastic condition; the other is to make the bells separately and attach them while still plastic to the body portion of the insulator. This latter process is employed for the larger insulators, and one rarely finds a German insulator that has punctured through the joint. Such joints have been attempted a number of times on insulators in the United States, but always without success. The author is convinced that the European clays lend themselves much more readily to this process than do American clays.

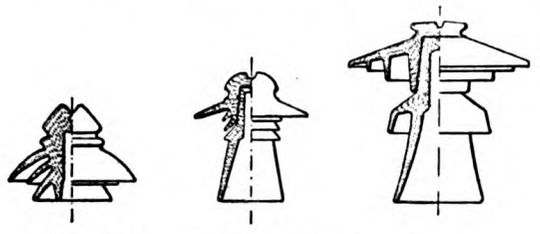
Another insulator used extensively in Europe is illustrated in Fig. 10. This type, known as the "rillen" insulator, depends upon



FIGS. 7 AND 8.—UNDERHANGING INSULATORS.

the principle of having a number of "rillen" or grooves cut into the body shell at a point well up on the body shell so that they are protected from most direct rain by the overhanging head of the insulator. The value of a number of these insignificant grooves is remarkable. The Ph. Rosenthal Co., who produced this insulator, have developed it for higher voltages into the insulator shown in Fig. 11. This insulator is said to be serviceable for voltages up to and including 66,000 volts. In its manufacture the projecting flanges are all made separately and joined in the green condition to the body portion of the insulator. The production of this type of insulator was attempted in the United States some years ago, but was abandoned on account of the difficulties of manufacture. Another insulator design, the uniqueness of which makes it worthy of attention, is shown in Fig. 12. This insulator would naturally fall in the same class as Figs. 5 and 6, since its enormous size would make its production and installation exceedingly expensive, if not prohibitive.

In Germany the Hermsdorf Porzellanfabrik have placed on the market a large variety of underhung insulators. Those most highly recommended are of the types shown in Figs. 13, 14 and 15. Figs. 13 and 14 may be properly classed with the American type shown in



FIGS. 9, 10 AND 11.—GERMAN INSULATORS.

Fig. 7. Fig. 13, however, has a straight hole for the upper loop which overcomes the danger of water collecting in this exposed opening. It also has the advantage of an extending shell which, of course, materially increases its efficiency. Fig. 14 is practically the same as Fig. 7 in principle, but has incorporated as nearly as possible the type of the old "delta glocke" in an underhung insulator. The European underhung insulator which most nearly resembles Fig. 8 is shown in Fig. 15. This insulator is notable on account of having a thin enamelled sheet-steel umbrella in place of the first porcelain shell. While the value of the insulator when dry is thus slightly reduced, its value under rain is increased, since with enamelled steel a flatter, wider umbrella can be made than with an equal weight of porcelain.

Comparison of European and American Insulators.—Any attempt to compare, from the data available, the relative efficiency of European and American insulators would be probably very misleading, except in cases where the tests were made at the same time and place and with the same testing equipment. Friese, in writing of high-voltage insulators, figured the efficiency on the basis of the formula: $A \times B =$ insulating value, where $A = \frac{\text{insulating value under rain}}{\text{insulating value in dry condition}}$ and $B = \frac{\text{insulating value under rain.}}{\text{weight of the insulator.}}$

As an example he compared a Hermsdorf "delta glocke" insulator and an American insulator tested under the same conditions and having practically the same value for A. The result was as follows:—

	Under rain.	Dry.	W'ght.	A	B	Insulating value.	Area of top shell.	H'ght.
	Volts.	Volts.	Grms.				sq.cm.	cm.
German "delta-glocke"	49,000	93,000	2,125	0·53	23·0	12	240	19·5
American insulator	49,000	92,000	2,910	0·53	16·8	9	325	23·0

Thus, a "delta glocke" insulator of approximately 7 in. diameter by $7\frac{3}{4}$ in. high and weighing 4·7 lb. was shown to have an insulating value equal to that possessed by an American insulator of 8 in. diameter by 9 in. high and weighing 6·4 lb. These figures prove beyond dispute the high efficiency of the "delta glocke" type of insulator. European engineers, however, have followed the American example in the design of insulators for higher voltages and have increased the size with more than a proportionate increase in weight.

On both sides of the ocean this has resulted in the discovery that size alone does not produce efficiency in an insulator, but that the volume of porcelain contained therein and the amount of surface as

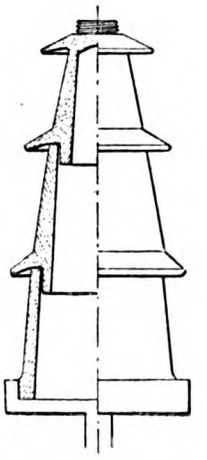


FIG. 12—KUHLMANN INSULATOR.

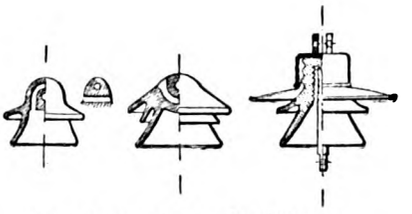

FIGS 13, 14 AND 15.—SUSPENSION INSULATORS.

compared with the weight of the mass bear a definite relation to the efficiency of the insulator produced. That the insulating efficiency of a porcelain mass does not increase in direct ratio with its thickness has been known for several years. Researches which the writer is pursuing upon the insulating value of porcelains from European materials, are not as yet in shape for publication, but herewith are given, in Fig. 16, the most recently published curve showing puncture voltages of various thicknesses of German porcelains. On the same diagram is shown a curve of puncture voltages for various thicknesses of American porcelains. While the two curves were not made under the same test conditions, and, therefore, the actual values therein contained cannot be compared, yet it is interesting to note the fact that the curves run practically parallel, which indicates that the influence of thickness upon insulating value is the same for European as for American porcelains. The idea prevails in the United States that German products are prepared to stand a higher test than American insulators. Based upon the relation of test voltage to working voltage, however, the German insulator is not ordinarily as severely tested as the American insulator. In fact, the Verband Deutscher Elektrotechniker specifies a much more moderate test. These lower test voltages and the above data offered by Friese regarding the "delta glocke" insulator are probably responsible for the impression that the German insulator is uniformly lighter for a given working voltage than the American insulator. When the weight, however, is compared with the test voltage instead of working voltage, it is found that the insulators of both lands fall within the same area. Thus it is seen that engineers, both in Europe and America, have reached the same point and can go no farther.

In the study of insulators it may be said that all transmission insulators may be divided into two classes: (*a*) Those constructed with the idea that they shall possess enough dry surface at all times to provide the necessary insulation; (*b*) those constructed upon the principle that porcelain surfaces, even when damp, possess a certain insulating value, and if enough distance is provided the required insulation is secured. The fault with class (*a*) is that it is practically impossible to prevent some rain from spattering from the exposed surfaces on to the protected surfaces of the overhanging shell. This small amount of water is volatilised by surface leakage and forms steam, which rises, and hence remains under the overhanging shells of the insulator. If the rain is of any great duration, this accumulation of steam and vapour reduces the insulating value of the so-called dry surfaces to that of exposed surfaces of porcelain. If the insulator is selected with a sufficient factor of safety the sum of the insulating values of these wet surfaces, plus the insulating value of the inside surface of the centre, which generally remains dry, since no spattering can reach it, furnish sufficient insulation to prevent interference with service. All the types illustrated belong to this

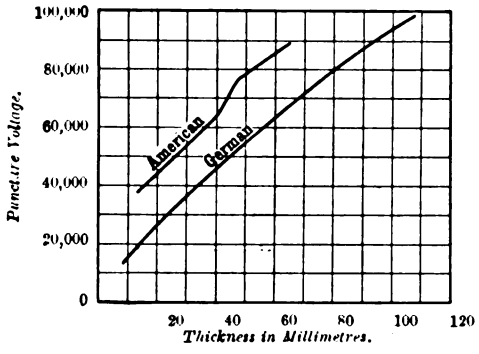

Fig. 16.—Dielectric Strength of Porcelain.

class, with the exception of Fig. 12, which plainly belong to class (*b*). The fault with class (*b*) is that it requires so long a surface that the weight, if designed as here shown, is almost prohibitive, and yet the principle of class (*b*) provides the only certain means of insulation.

The principles of these two classes may be combined to produce a reasonably light, efficient insulator, and the writer believes that the solution of the insulator problem for voltages between 60,000 and 100,000 volts is along the following line: It is known that a plain glazed porcelain tube (class *b*) 1 ft. long and 3 in. in diameter, when exposed to a rain of 1 in. in five minutes' precipitation, possesses an insulating value of about 30,000 volts. If this tube is corrugated uniformly over its entire length, it is found that its value under the same test is increased to about 50,000 volts. However, if the tube has undercut corrugations, the surface distance between ends is not only materially increased, but there is some protected surface to aid in insulation. These undercut surfaces not only have the advantage of being small and thus not permitting of any considerable vapour accumulation, but the fact that they are shallow enables the wind to free them of the vapour as fast as it accumulates. This may explain the remarkable value of the "rillen" in the Rosenthal insulator, Fig. 10. Be the explanation of the phenomena what it may, it has been proved beyond dispute that such a corrugated tube, 12 in. long and 3 in. in diameter, under rain test as above, possesses a value of about 100,000 volts. Moreover, a tube being of uniform surface design, the value may be increased by merely increasing the length of the tube.

The writer suggests the insulator shown in Fig. 17. The advantages of such an insulator are many. It is not so heavy as the ordinary 60,000-volt insulator. It can be handled with much less danger of breakage in construction and when in place is practically safe against destruction by miscreants. In case of lightning it has no extending shells to be broken by the shock. The temporary short circuit passes along its face rather than follows the small corrugations, with the result that it passes such a shock uninjured, whereas with the ordinary shell insulator destruction is certain. In the case of rain its exposed surface is small as compared with most 60,000-volt insulators, hence if it is necessary to keep the protected surfaces absolutely dry by surface leakage, the loss will be comparatively small. The only drawback to such an insulator is the difficulty of manufacture. However, such tubes are made with comparatively little loss in Europe, hence it may be assumed that a little experience would enable the American manufacturer to produce them with equal success.

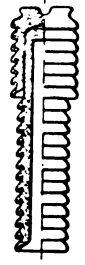

Fig. 17. Suggested Type.

In closing, the writer calls attention to what in his opinion is the greatest hindrance to progress in insulator development and which has caused more false impressions and trouble than all other causes combined. Reference is made to the absolute absence of anything like a uniform test for transmission insulators. Voltage and precipitation are spoken of as though they were standard factors not capable of influence by any varying condition. A given voltage may refer to a test with an equipment of 10 kw. rating or a 1,000 kw. equipment. A given precipitation may refer to a fine driving mist or it may refer to a gentle downpour. And so with all the other data that are recorded on insulator tests. It would be far better to have all tests with moderate equipment of a given type under standard specifications, and thus have all data comparable, than to have the present system.

REPORT OF THE BRITISH ASSOCIATION COMMITTEE ON PRACTICAL STANDARDS FOR ELECTRICAL MEASUREMENTS.*

The report of the International Conference on Electrical Units and Standards held in London in October, 1908, was printed as an appendix to last year's report. In January, 1910, the Board of Trade took action in accordance with the recommendations of the report, and an Order in Council relating to electrical units, dated January 10th, which contains definitions of the English standards of resistance, current and E.M.F. in conformity with the definitions adopted by the Congress, has been issued. This is printed as an appendix.

In accordance with a scheme approved by the International Scientific Committee appointed by Lord Rayleigh at the London Conference, international co-operative work on electric standards has this year been carried out at the Bureau of Standards, Washington. It was arranged that representatives of the Bureau of Standards, the Laboratoire Central d'Electricité, Paris, the Physikalisch-Technische Reichsanstalt, Berlin, and of the National Physical Laboratory should take part in the work. The representatives of the Bureau of Standards were Prof. E. B. Rosa and Dr. F. A. Wolff, and the European delegates were Prof. W. Jaeger, Prof. F. Laporte and Mr. F. E. Smith. Prof. S. W. Stratton kindly offered the facilities of the Bureau of Standards for the investigation, and, in his capacity as treasurer of the International Committee, was able to secure the funds to defray expenses. Towards this object the governing bodies of the American Institute of Electrical Engineers, the National Electric Light Association, the Association of Edison Illuminating Companies and the Illuminating Engineering Society most generously subscribed £100 each. Some smaller contributions were also received.

The primary object of the meeting was to determine the E.M.F. of the Weston normal cell in terms of the international units of resistance and current. At the same time it was necessary to clear up certain outstanding problems on the standard cell and the silver voltameter. Previous to the meeting a great deal of experimental work had been done at each of the four institutions, and the results obtained were compared before deciding on a programme of experimental work.

The European delegates took with them from their own laboratories a considerable quantity of apparatus and chemicals, together with standards of E.M.F., resistance and mass. The results of the meeting are very valuable, and a full report is in process of preparation.

Another careful research on the silver voltameter has been made during the year by Prof. F. Laporte at the Laboratoire Central d'Electricité. Prof. Laporte shows that the result obtained in 1908 by Profs. Janet, de la Gorce and himself is subject to an appreciable error, owing to the use of silver nitrate, now known to be impure. With carefully prepared nitrate, and using the Rayleigh form of voltameter, he obtains 1·11829 milligram per coulomb for the electrochemical equivalent of silver, the current being measured in terms of the Weston cell as 1·01830 volts at 17°C. and the international ohm as realised at the National Physical Laboratory. The unit of current was, therefore, the same as that used by Smith, Mather and Lowry in 1908, and the value for the electro-chemical equivalent found by Prof. Laporte is in very close agreement with the value 1·11827 obtained by the British investigators.

* Report presented to Section A at Sheffield. The Committee consists of Lord Rayleigh (chairman), Dr. R. T. Glazebrook (secretary), Profs. J. Perry, W. G. Adams, and G. Carey Foster, Sir Oliver Lodge, Dr. A. Muirhead, Sir W. H. Preece, Profs. A. Schuster, J. A. Fleming and Sir J. J. Thomson, Dr. W. N. Shaw, Dr. J. T. Bottomley, Rev. T. C. Fitzpatrick, Dr. G. Johnstone Stoney, Prof. S. P. Thompson, Mr. J. Rennie, Principal E. H. Griffiths, Sir Arthur Rücker, Prof. H. L. Callendar, and Messrs. G. Matthey, T. Mather and F. E. Smith.

Digitized by Google

The General Committee at Winnipeg accepted the recommendation of the Council and the Committee of Section A in favour of the republication of all the Reports of the Electrical Standards Committee. Suitable arrangements for the work have, therefore, been made, and the material is now with the printer, but in consequence of the absence of Mr. F. E. Smith in America, and the work of preparation required for this, progress has necessarily been slow.

With regard to progress in electrical standardising work at the National Physical Laboratory, the Lorenz apparatus is practically complete, and some preliminary electrical measurements will, it is hoped, be made in October of the present year. The Ayrton-Jones current balance continues to work most satisfactorily; small and gradual changes in E.M.F. of Weston cells, amounting to less than three parts in 100,000 have been detected by its aid.

The results of the investigation on cadmium amalgams at the National Physical Laboratory were incorporated in a Paper read before the Physical Society last February. It may be useful to give here the limits of temperature between which various amalgams may be most usefully employed in the Weston normal cell :—

Percentage of cadmium in the amalgam.	Lower limit. Deg C.	Upper limit. Deg. C.
6	Below 0	about 27·7
7	,,	,, 34·6
8	,,	,, 41·0
9	,,	,, 46·0
10	,,	,, 51·0
11	about 0	,, 56·0
12	,, 8·7	,, 60·0
12½	,, 12·1	above 60·0
13	,, 16·1	,, 60·0
14	,, 24·0	,, 60·0
15	,, 32·5	,, 60·0

The degree of reproducibility which is now obtainable with the Weston cell far surpasses what it was five years ago. At the National Physical Laboratory 67 cells were tested in 1909, and of these 60 agreed with the Laboratory standards within one part in 10,000. What is not understood at present is the occurrence of strange hysteresis effects in a few cells. The E.M.F. of such cells may be normal at first, but changes comparatively rapidly with time. Indeed, a large hysteresis effect in a cell appears to be an indication that the E.M.F. will not remain constant with time, whereas its absence is in general an indication of constancy.

In view of the fact that the republication of the Reports is not yet completed, the Committee recommended that they be reappointed, that Lord Rayleigh be chairman, and Dr. R. T. Glazebrook, secretary. The Order in Council relating to Electrical Standards is contained in an appendix to the report.

COOKING AND HEATING BY ELECTRICITY.*

BY P. A. BATES.

The result of recent activity among the manufacturers of heating and cooking apparatus is that to-day we have an assortment of electrically operated devices, available at reasonable prices, which are thoroughly reliable and suitable for the purposes for which they are designed. In fact, being free from many of the disadvantages of older types, in which fuel is burned directly, their superiority for domestic use is marked. One of the very important advantages of this method of cooking and heating is its freedom from fire risk.

The cost of cooking by electricity depends, of course, upon the cost of the electric current available. Many, however, are satisfied to dismiss the question of cooking by electricity with the thought or statement that it would be impossible for electricity, produced by the roundabout means of the steam boiler, steam engine, dynamo and transmission wires to compete upon a cost basis with the direct use of coal for cooking purposes. Those who argue upon this basis lose sight of the advance which has been made by gas, also a product of coal, in this field, where it very frequently is able to show a decided saving as compared with the direct use of coal for the same purposes. The reason for this is, of course, the possibility of confining the heat of the gas flame and applying it only where needed. This is also true where electricity is used, only to an even greater degree.

The case with which the electric current may be switched on or off makes this source of heat even more convenient than gas, and the ability to confine and apply the heat where wanted is much greater with the former than with the latter. In fact, it has been found that with the ordinary gas range 15 per cent. of the heat produced is usefully applied, while with the various high-grade electrical cooking devices now obtainable 70 per cent. or more of the heat produced is utilised.

In order that electricity should compete successfully upon the basis of cost alone with gas or coal for cooking and heating purposes, the rates ordinarily prevailing throughout the United States must be reduced; and electric lighting companies generally are only just beginning to realise the possibilities in this line and to make systematic efforts to obtain this class of business.

Even at somewhat greater cost of operation, electric cooking, in common with other electrical devices, has many advantages. The rapidity with which food may be cooked by the use of electricity, the uniformity of temperature obtained, which makes cooking by the clock a possibility, the great comfort and convenience, the cleanliness and freedom from smoke and smell, make it ideal for all places where these advantages are of importance. As might be expected, the results obtained with this method are beyond all comparison with those from any of the older methods.

Unfortunately, this ideal method of cooking has not been taken hold of by the manufacturers with sufficient enterprise and business judgment, the result being that there are few noteworthy installations, and of these the number that have been tested with a view to obtaining exact and useful information as to actual performance is astonishingly small. A most interesting installation of this kind which has come under my direction, is that installed in one of the prominent club houses in New York city about three years ago. It represents a type well suited to the requirements of any club house, large residence or hotel, where it is desired to secure the best of service obtainable. The author then gives a menu, with the time required for the preparation of each item, to illustrate the service of which these devices are capable.

There are two important reasons for the superiority of the actual cooking accomplished by the electric method. One is inherent to all electrical heating and cooking devices—namely, the entire absence of all flame, gas, smoke or dirt; the other is a result of the design of this particular type of apparatus. Each broiler unit is equipped with heating coils on both vertical sides, and the spider containing the steak, chop, chicken, toast or other article to be cooked is inserted in a vertical position between the two sources of intense heat. The current, therefore, passing through the coils produces heat simultaneously on both sides. This has the double effect of halving the time necessary to do the cooking, and, in the case of meat, the outer tissues are at once seared, thus tending to prevent the escape of the natural juices which otherwise often drip into the fire and are lost. A chop or steak, for instance, cooked in an electric broiler will be juicy, but evenly done throughout, and absolutely free from all gas or odour. Compare this result with a similar cut cooked over a fire, overdone on the surface, underdone in the centre, charred in spots by the fire or burning grease as it often is, with most of the juice of the meat lost and a decided taste and odour of the fire.

The time required for the preparation of articles of food in an electric grill is important as a determining factor in the cost of the cooking process. This is particularly true in the case of a club or other restaurant, because of its bearing upon the quality of the service rendered, and the fact that the cooking can be accomplished in half the time means that a smaller grill may be installed. The menu mentioned above illustrates these points, and it is evident that the cost of cooking is but a small part of the price charged for the service or even of the market value of the unprepared food. At a rate for electric current of 1½d. or less the cost of the current required for cooking becomes almost negligible. Contrary to what might be expected, the repairs on these electric cooking devices are surprisingly small.

In the line of heating, the field for the use of electricity is more limited, being confined to special applications. General heating by electricity, except under very special conditions, is, and probably always will be, too expensive for serious consideration. There are, however, many applications where the advantages of electrical heating are sufficient to outweigh its greater cost. To meet these conditions, a number of electric heating devices have been developed and placed upon the market. Perhaps the most useful of these for home use is the electric radiator, the advantages of which over a portable oil stove, that has a very bad effect on the air of a room, need scarcely be mentioned.

*Abstract of an article in the "Electrical Review and Western Electrician."

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Digitized by Google

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*
(This charge includes all Supplements.)
Vols. I to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John E. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [Abroad 13s.
VOL. I. Price 12s. 6d. post free, abroad 13s. VOL. II. Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d. [Price 10s. 6d. nett.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.* [Price 3s. nett.

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post, in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-second issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for August 19.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

THE BRITISH ASSOCIATION.

Quite apart from the calendar, signs are not wanting that the Long Vacation is drawing towards a close, and that the holiday season has practically come to an end. The most significant of these indications is the meeting of the British Association, held this year at Sheffield. For the teacher this great gathering serves a double purpose; it provides a pleasant termination to a few weeks of idleness, and it also serves as a gentle reminder of the labours in store. Quite apart from this, however, it brings technical men into intimate contact with workers in pure science, to the infinite advantage of both; and, in addition, it provides the public with an admirable opportunity of getting an insight into scientific matters at first hand, instead of having to rely on the sensational information disseminated by the daily papers. There is, of course, always the danger that statements made at British Association meetings may be misinterpreted by the uninitiated, and it is even possible that speakers may, in their endeavour to get down to the level of the layman, give utterance to remarks which are hardly warranted by facts. This is a matter that requires very careful watching, for however "popular" the British Association may become, it would be a fatal mistake to allow sensationalism to bring its veracity into dispute.

The primary object of the British Association is, as its title implies, the furtherance of scientific work—"the advancement of science"—and there can be no doubt that it has been the means of providing a large number of scientific men with the facilities for conducting important researches. The annual meeting is, after all, but a portion of its work, and an enormous amount of patient investigation goes on during the 12 months while the whole organisation is lying dormant—at all events, so far as the public are

Digitized by Google

concerned. It would, therefore, seem that, since the lay members and associates bear a considerable share of the piper's payment, they should have a certain voice in the calling of the tune. At present they are, of course, regaled with popular lectures, receptions, garden parties and other functions of a more or less tedious nature, and in this way undoubtedly become pleasurably excited and fatigued for the modest sum of one guinea. The expense of these festivities is largely borne by the city or town, and certain of its private residents, acting as hosts for the time being. The bulk of the numerous guineas is, therefore, available for general expenses and for subsidising research. This is all very nice, and generally goes off very well; but perhaps one may be permitted to question whether it is quite the thing that the founders of the British Association had in view. It may be asked whether the unscientific members are not to be taken more seriously, and given a more active part in the "advancement of science." The numbers of those attending this year's meeting were less than they were two years ago at Dublin, and it is becoming more and more evident as years go by that the Papers and discussions are becoming more and more difficult of comprehension by the uninitiated.

Of course, there are still many people who are only too willing to sit, and perchance to sleep, in a stuffy room for three or four hours drinking in the words of wisdom that fall from the lips of the mighty, and then to go away without an intelligent comprehension of a single sentence. It is these people, more numerous than is generally thought, but undoubtedly becoming less year by year, who are intensely loyal to the Association, but receive very little in return for their loyalty. Unquestionably the problem is a difficult one, and the solution may lie in the direction of ignoring this class and frankly admitting that the day of the semi-popular Paper and discussion is over. We cannot help thinking that, in some respects, this would be an unfortunate step. There is much to be said for Sir GEORGE REID'S plea for the great men to *know* what they are talking about, so that they can explain it in plain English to others. Apparently in no section is this more desirable than in Section A (Mathematics and Physics), where physical science seems to be becoming increasingly mysterious. Indeed, it would seem that no two physicists can agree on any one subject except the excellence of an author's Paper, and it is refreshing to find that there is unanimity on at least one topic of discussion. Speculation is rife as to what one authority could do with a substance if another one could produce it for him. Every year the debates partake more of the nature of gladiatorial combats, and every year witnesses the announcement of some extraordinary feat which is received with fierce criticism and thereafter sinks into well-deserved oblivion. So the great British Association goes on. The popularity of sections waxes and wanes, that of Section G not being very great at the present moment in spite of the able presidency of Prof. DALBY. All interest seems to centre on those whom a distinguished scientist has described as the para-physicists, who employ their time in estimating the density of the ether and in counting electrons. What it will all lead to nobody knows, but there is just a suspicion of its being slightly overdone at the British Association.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Wireless Telephones and How They Work. By J. ERSKINE-MURRAY. (London: Crosby, Lockwood & Son.) Pp. 60. 1s. 6d. net.

This little book of 60 pages is intended to be understood by the bookstall public. It opens with an interesting exposition of the most elementary facts of acoustics, of the microphone and of the telephone receiver. Here all the science is expressed in the simplest language, with, however, greater loss of precision than is excusable. The author's difficulties in this respect become more pronounced when he explains the production and propagation of electric waves, and they continue right through the brief discussion of wireless telephone apparatus and the explanation of resonance. In this latter matter the author strives after simplicity by making a fallacious application of the principle of the superposition of small motions, an application that will startle those who understand the principle in the orthodox way. The author is happier when discoursing patriotically on the value of wireless communication between the parts of the Empire.

W. H. E.

Die Elektrochemischen Patentschriften der Vereinegten Staaten von Amerika. By Dr. P. FERCHLAND. Vol. I. "Elektrothermische Verfahren und Apparate: Entladungen durch Gase." Vol. XXXIII. of "Monographien über angewandte Elektrochemie." (Halle a. S.: Wilhelm Knapp.) Pp. vi. +204. M12.

Dr. Ferchland has already written for this series some monographs upon the electrochemical patents of Germany and England, and we are now indebted to him for the present one under review. In some respects the methods of the American Patent Office vary considerably from those adopted by the British and German offices, but of recent years the tendency has been for the American methods to approach the German, and, of course, since the new Patent Act, our own methods are also much more akin to the German than heretofore. The Americans are very particular that the patent shall only be given to the first and actual discoverer of a process; therefore, if anyone else takes out a patent the original discoverer can upset the patent by proving that he was the actual discoverer, even though he may not have published the fact. Greater latitude is also given for working the process before the actual patent is published; this, of course, is a very great help. Considering that 900,000 patents have been taken out in America against 200,000 in Germany, the work of Dr. Ferchland must have been extremely difficult and arduous. It is really not possible in reviewing such a book to discuss the individual patents included in its pages, except to state that any particular patent we have searched for we have been able to find. The description of each individual patent is necessarily short, but the author has succeeded in being concise, and the illustrations very much help the text. We consider the book a very useful monograph.

Nightshade. By PAUL GWYNNE. (London: Constable & Co.) Pp. x. +431. 6s.

Having received a copy of this book for review, we naturally expected to find some scientific basis for the story. This basis, however, is very slender. An old "scientist" has devised a remarkable lamp which enables the blind more or less to see when under its influence. Hence it is termed "Nightshade," from analogy to nightshade, or belladonna, which has the property of dilating the pupil of the eye. It is the special radiation of this lamp which is effective. Whether the blind are thus enabled to see by ultra-violet light, or what the type of radiation is, we are not told, but apparently the blind musician on whom the experiment is tried sees visions of the past and other things invisible to ordinary mortals. We need scarcely say that a love story, of a rather tragic kind, is wrapped up with the fate of the musician, and those of our readers who are fond of the weirdly impossible will find this book as good a companion on a holiday as most of the recent novels to be found at the sea-side

THE BRITISH ASSOCIATION AT SHEFFIELD.

(FROM OUR SPECIAL CORRESPONDENT.)

Wednesday, August 31st.

In spite of all the attractions offered by Sheffield, no meeting of the British Association has been held here since 1879. This is, of course, a long period in the life of any scientific institution, and it has also been full of changes for the City of Sheffield itself, enormous developments having taken place within the last 15 years. Not the least pleasant feature of the meeting is the accessibility of the place from almost all parts of England, and perhaps one may pay a tribute to the Great Central Railway for that magnificent train which performs a non-stop run from London in just under three hours. In spite of the exceedingly heavy traffic, this train ran into Sheffield this evening just two minutes before time. Unfortunately, however, passengers who travelled by it, or by any train arriving after 6 p.m., were not in time to get into the Reception Room. Perhaps, in future years, arrangements might be made to keep the latter open a little later on the first day, as many people arrived only to find it impossible to get a ticket for the Presidential Address in the evening.

The President this year, Dr. T. G. Bonney, F.R.S., is a distinguished geologist and thus his address almost necessarily contained nothing of special interest to readers of THE ELECTRICIAN. He succeeds Sir J. J. Thomson who is present at the meeting.

Thursday, September 1st.

Section committees commenced work as early as 9:15 this morning, and everybody has been hard at it ever since. In Section A (Mathematical and Physical Science) Prof. E. W. Hobson delivered an admirable Presidential Address dealing largely with the teaching of mathematics. While admitting that the mathematical knowledge required by a student of physics or engineering is different from, and not so thorough as, that of the pure mathematician, yet he pointed out the danger of a too narrow acquaintance with the subject. An abstract of the address has already appeared in these columns, and it is only necessary here to call attention to Prof. Hobson's warning that it is not sufficient for a student to learn off a few formulæ, but that the principles also must be learnt. The science of mathematics is too delicate a tool for rule of thumb use. Presumably, Prof. Hobson would be quite willing to admit that certain eminent engineers and physicists are by no means brilliant mathematicians, but such an admission does not have the slightest effect on his argument.

On the conclusion of the Presidential Address, Prof. Sir J. J. Thomson read a Paper on "Positive Electricity." Following the Papers came the reports of committees. One report related to experiments for improving the construction of practical standards for electrical measurements. In the course of this report it appears that the Ayrton-Jones current balance installed some time ago at the National Physical Laboratory is working most satisfactorily. Small and gradual changes in the E.M.F. of Weston cells, amounting to less than three parts in a hundred thousand have been detected by its aid. The Weston cell can now be reproduced with great exactness, but the occurrence of strange hysteresis effects in a few cells is not at all understood.

In the report of the committee on Magnetic Observations at Falmouth Observatory it is stated that the responsibility for the magnetic and meteorological work of Kew and Eskdalemuir now rests with the Meteorological Office, and it is suggested that Dr. Shaw be added to the committee, and be asked to act as Secretary.

It is not often that Section F. (Economic Science and Statistics) is invaded by the electrical engineer, but this year the very first Paper on the list was on "The Price of Electricity," by Mr. E. W. Cowan, of which a lengthy abstract will be found elsewhere.

A lively discussion followed the reading of this Paper, the first speaker being Mr. S. L. Pearce, chief engineer to the Manchester Corporation Electricity Supply Department. On the whole he expressed agreement with the author, but he emphasised the difficulty of converting principles into a practical tariff system. There was no doubt that flexibility was greatly to be desired provided it was not of such a nature as to give undue preference to any consumers. He did not believe in the popular contention that the selling price should be proportional to the cost of production; indeed, he agreed with Mr. Cowan that energy could be sold at a profit when apparently it was being sold for less than it cost to produce. As an example of this he called attention to the fact that less than 10 years ago the capital cost of new plant was about £8 per kilowatt; to-day it was about £3. It was obvious that it would pay well to put in modern plant for new consumers and supply them at a rate based on this plant costing £3 per kilowatt, even though this price happened to be less than the average cost of production with the whole of the plant. In short, he contended that a remission of capital charges should be made to large consumers. He considered that the "equal profit" basis was fallacious, as the same profits could not be made on different units under the flat-rate system.

Mr. S. J. Watson called attention to the danger of regarding any branch of supply as a by-product. By offering it at an extremely low price, which might pay very well in the by-product stage, the demand for it might be cultivated to such an extent that it might become the main branch of the business and result in a loss.

Mr. A. J. Cridge, of Sheffield, thought that it was very unsound to base any tariff on the number of lamps or kilowatts of plant installed, as such a course tended to keep down the size of the installation.

Prof. Ashley expressed surprise that the principles of Mr. Cowan's Paper could ever be doubted by electricians. Personally, he considered that electricity supply was completely on all fours with the railway services, and the problem of a tariff should be worked out on similar lines.

Mr. W. B. Woodhouse, chief engineer to the Yorkshire Electric Power Co., said that Mr. Cowan's Paper dealt with a subject of very considerable importance, and in general he found himself in agreement with the author's argument against the insistence on a basis of equal profits from all consumers. If the expediency and justice of such a difference of basis were admitted it seemed to him that it must be considered whether there were limitations to this difference, and if so, what they were. The question raised by Mr. Cowan was whether the production of electricity to meet the composite demand for light, heat and power was a joint supply, of which a part or parts might be regarded as a by-product. If this were answered in the affirmative then each market might be considered separately without detriment to the others, provided that the price of the commodity for any particular use or demand did not fall below the cost of producing the extra amount of electricity to meet that demand. This was the equitable minimum price, because any price below this would reduce the total profit and thereby affect the other markets. The superior limit of price, was "what it will fetch," and the satisfaction of the demand at prices between these limits must prove profitable. Regarding the matter as one of ordinary trading the market price, or "what it will fetch," was the fair price for the commodity as a whole, and on the face of it the fair price for each class of supply. This latter deduction, however, was open to question if the various classes were not definite and separate. Mr. Cowan had considered four kinds of use, viz., light, heat, power and electrolytic purposes, but these classes might with equal reason be again subdivided, and it might be argued as a logical outcome that the price of electricity for power should depend on the trade or purpose for which the power was used.

Digitized by Google

Or, again, that where two processes, such as thermal and mechanical, were in use to produce similar articles, the supplier of electricity would be justified in charging different prices. The supply of electricity, although primarily a trading concern, and therefore subject to the ordinary motives of such concerns, was a public service, and because it enjoyed certain privileges also carried certain obligations. The endeavour to earn the maximum profit consistent with security had to be tempered by a sense of equity. The privileges granted must not be abused, and security from paralysing State restrictions, such as the American undertakings had been subjected to lately, was best obtained by so adjusting prices that the profit from any one class of consumer was not unreasonable. This he (Mr. Woodhouse) thought was largely the reason why suppliers of electricity had paid more attention to the relationship between price and cost than supply and demand. There was a further reason, in many cases, viz., that the margin between cost and market price had been so small as to keep the supplier more concerned with the lower limit of price than the higher. In view of the many new uses to which electricity was being put he thought Mr. Cowan's Paper a most opportune one, and the adoption of the principle he had so clearly argued should assist such development.

Prof. Dalby's Presidential Address to Section G has appeared in abstract in THE ELECTRICIAN, and it is therefore unnecessary to deal with it here. The attendance was disappointing, especially in view of the importance of the engineering industry in Sheffield. In proposing a vote of thanks, Mr. Charles Hawksley said that Prof. Dalby was peculiarly fitted to deal with problems affecting railways. He was an example of the professor who was not a mere theorist. The scientific professor was very useful, but when they had the scientific professor combined with the man of practical knowledge, then they had the professor of the ideal type. Prof. Ripper, in seconding the proposal, echoed the remarks of Mr. Hawksley. Subsequently, Prof. Ripper described a method of testing lathe tool steel, and gave a demonstration in his laboratory.

In the afternoon, visits were paid to several of the large works of engineering interest in the locality, and in the evening the Lord Mayor and Lady Mayoress held a reception in the Town Hall.

Friday, September 2nd.

Section A opened this morning, in conjunction with Section B, to hear a report on Gaseous Combustion by Dr. Wm. A. Bone, F.R.S. This proved to be a most useful and instructive piece of work, the author describing the researches of Dixon and his colleagues, and exhibiting some beautiful photographs showing the progress of an explosion in glass tubes. In the course of the discussion Sir J. J. Thomson suggested that the velocity of the explosion might depend on the propagation of ions in advance of the explosion wave in such a way as to ionise the gases and thus prepare the way, as it were, for the subsequent combustion. He merely put this forward as a possible explanation of the great rapidity of movement of the explosion. It could easily be tried by causing the explosion to take place within a magnetic field. If ions were propagated they would be turned aside and hence the rate of propagation of the explosion wave would be altered. Subsequently Prof. Dixon said he had tried this experiment but could detect no change. Sir Oliver Lodge agreed with Sir J. J. Thomson, and further remarked on the enormous influence which surfaces had on combustion. The temperature of the surface was of great importance, and complete combustion could never take place if the combustibles were in contact with a cool surface such as that of water. Referring to the relation between the velocity of propagation of an explosion and that of sound, he said that nothing could travel through a given gas with a greater velocity than that of sound in the same gas. At the same time, although the velocity of sound under ordinary conditions was only 1,100 ft. per second, yet it was common knowledge that the initial velocity of many projectiles was double this. To reconcile these two statements it was only necessary to remember that the projectile compressed the air immediately in front of it thus raising the temperature, and thereby raising the velocity of sound in that air to a value either equal to or in excess of that of the projectile. Hence the possibility of great speeds of projectiles.

Prof. Dixon, in discussing the effect of the presence of moisture in explosive mixtures, maintained that although moisture was necessary to start the action it was not necessary for the continuance. This statement at once brought Prof. Armstrong to his feet and led him to remark that Prof. Dixon had approached very near to a point which he had advocated for many years, viz., that no interaction of any kind could take place between two molecules neither of which was an electrolyte. Hence the necessity for water being present, and it must not be pure water—that would not do—it must be dirty water, that was, water containing something capable of turning the non-conducting pure water into a conductor. Sir J. J. Thomson then asked Prof. Armstrong if he would explain what he meant by the expression "electrolyte," and the reply was that it was a substance which would convey a current and be decomposed in the process. Sir J. J. Thomson: "Well, anything can do that." Prof. Armstrong: "Can pure water carry a current?" Sir J. J. Thomson: "Yes." Prof. Armstrong thought that this would never be proved because nobody could procure pure water. He believed that it would be found that a gas pure and simple was not capable of carrying a current, and in reply to this Sir J. J. Thomson said he was prepared to get a current through it if Prof. Armstrong would provide the pure gas. At this point, a highly diverting discussion came to an end.

The next Paper on the list was on "The Molecular Weight of Radium Emanation," by Sir Wm. Ramsay and Dr. R. W. Gray. The results of their experiments gave 221 as the molecular weight of the emanation, which figure agrees pretty closely with that of 222·5 obtained on the basis of the disintegration theory. The experiments, of which there were five in number, were conducted with a view to obtaining the weight of a known small volume of the emanation, the amount used being of the order of a tenth of a cubic millimetre. The principal point of the work was an exceedingly delicate balance capable of weighing to the $\frac{1}{5000000}$ of a milligram. This balance was made of quartz fibre, and its beam was about 6 cm. in length. Its weight was approximately half a gramme. It was supported by a single knife edge 0·5 mm. in length, and enclosed in an air tight metal lined case. The emanation was enclosed in a tiny glass tube which rested in one pan of the balance. The case was partially exhausted until equilibrium was obtained, and the pressure was read off. Next, the emanation was liberated by breaking the tube and the fragments replaced in the pan. Again the case was exhausted and filled alternately several times so as to wash out the tube thoroughly. Finally it was exhausted until the balance was again in equilibrium. This pressure was read off and by calculation it was possible to determine the weight of the emanation. The mean of the five experiments gave a molecular weight of 221. In chemical behaviour, the emanation was absolutely inert, and all its properties proved that it belonged to the inactive series of gases, while its atomic weight of 222·5 which the experiments confirmed, showed that it fell into the argon series in the periodic table, and filled the second vacant space below xenon. The authors, for these reasons proposed that, for the future, the radium emanation should be known by the name Niton, and that its chemical symbol should be Nt. This proposal at once evoked a small storm of protest, Sir J. J. Thomson leading the way, and suggesting that the matter should be referred to the forthcoming congress on radiology at Brussels. Other speakers objected to the name on account of its hybrid origin.

Dr. J. A. Crowther read a Paper on "The Number of Electrons in the Atom."

Section G devoted the morning to a discussion on the report of the committee appointed to investigate Gaseous Explosions.

Monday, September 5th.

No sectional meetings were held on Saturday, and many visitors seized the opportunity of going into the country for

Digitized by Google

the week-end. Yesterday morning a special service was held in the Parish Church, the sermon being preached by the Archbishop of York, and in the afternoon Sir Oliver Lodge delivered an excellent address in the Victoria Hall.

This morning opened well in Section G with a Paper by Mr. Philip Dawson, on "The Electrification of the London, Brighton & South Coast Railway between Victoria and London Bridge." The author showed a large number of slides illustrating the work, and gave a considerable amount of information which has already appeared in THE ELECTRICIAN. He said experience had shown that the acceleration obtained was quite as good as anything obtained by continuous current working, in spite of claims which had been put forward to the effect that the continuous motor would give superior results in this respect. Moreover, the extra weight involved by the transformers, &c., was only 10 per cent. Coming to the question of energy consumption, this was found to be about 70 to 80 watt-hours per ton-mile for the single-phase system, and 90 to 100 for continuous current. These figures referred to energy consumption at the generating station; on the trains themselves the figures were practically identical for both systems. The difference at the station arose out of the different transmission efficiencies. The power factor for the whole system was about 80 per cent. Turning to the motors, Mr. Dawson said that up to the present they had been a complete success. The commutators presented a black shiny appearance, very similar to that of a continuous-current machine, and although the sparking was more obvious than with direct current machines, yet it did not appear to do as much harm. This was demonstrated by the fact that the commutators would run for 50,000 miles before the necessity arose of turning them down. From the commencement they had not experienced the slightest trouble with the overhead work, and after eight months they could detect no appreciable wear of the conductor. Each bow strip required renewal after running for 15,000 miles. One of the most serious problems that they had to deal with was the lowering of the bow from 21 ft. in the yards to 13 ft. under bridges. This was a very difficult matter, but they had overcome it successfully, although in some instances the bow was only an inch and a half from the under surface of the bridge. Owing to the fact that porcelain was a strong, reliable substance under compression, but weak and unreliable under tension or flexion, he had adopted the former method throughout. He believed that the system described was the only one where the catenary suspensions were doubly insulated. A feature of interest was the oft-recurring St. Andrew's Cross painted on the iron work at intervals along the permanent way. These crosses marked positions where it was most economical for the motormen to switch off the current, and their adoption had resulted in a saving of from 5 per cent. to 10 per cent. in cost of energy. From diagrams which Mr. Dawson exhibited it appeared that the acceleration obtained was equal to over 1 mile per hour per second. Towards the end of his remarks he gave a brief description of an interesting petrol-electric inspection vehicle for use on the line. This little coach is equipped with a petrol engine and a small dynamo, and can be run to any part of the system with great rapidity. It is entirely independent of the overhead wires, and can therefore be employed when the current is switched off. The dynamo provides illumination and enables inspections and work to be carried out with the greatest ease.

In opening the discussion, Prof. Silvanus P. Thompson said he cordially agreed with Mr. Dawson that no one system, whether alternating or continuous current, could be set up as being suitable for all cases, but he thought that the author had shown how eminently suitable the single-phase system was for the specific purpose to which it had been applied in this particular instance. The problem with respect to short distances had already been solved, and he thought that for long distances single-phase working was greatly superior. Within the last few weeks he had seen drawings for a single-phase locomotive of no less than 2,000 H.P.

Other speakers in the discussion included Sir William White and Mr. Charles Hawksley.

The next Paper was by Mr. H. E. Wimperis "On the Use of an Accelerometer in the Measurement of Road Resistance and Horse-power." By the use of this instrument road resistances can be read off at sight, air resistances can be determined, the brake-horse-power exerted by an engine when running on the road can be found and other similar measurements can be made. An abstract of this Paper will appear in our next issue.

In the discussion, Prof. Dalby said that for years he and a number of his friends had been working at some instrument which would be capable of doing the things performed by that of Mr. Wimperis, and they had now given up all further work, as they were convinced that the problem was solved. Prof. Perry also warmly congratulated the author and remarked that the instrument described had undoubtedly a great future. Mr. Worby Beaumont also contributed to the discussion and gave demonstrations of the instrument on his car.

Prof. E. G. Coker then read a Paper on "The Cyclical Changes of Temperature in a Gas-engine Cylinder near the Walls." The following is a brief abstract.

Experiments described in October, 1908, showed that the temperature at the inner surface of a small gas-engine is about 240°C., and the cyclical variation usually less than 10°C. The steady conditions of low temperature at the wall-surface are maintained by the jacket-water, although the explosion of the gaseous mixture produces very great changes of temperature close to the walls. This variation has not hitherto been measured for a complete cycle owing to the difficulties which occur in measuring the highest temperature of the explosion. In order to obtain the cyclical variation near the walls, a couple was made of an alloy of 10 per cent. iridium and platinum, with a pure platinum wire, and this was secured in a metal plug so that it projected $\frac{1}{4}$ in. into the cylinder. On light loads and weak mixtures the couple remained unbroken, but near full load the platinum wire melted. Couples made from 10 per cent. alloys of iridium and rhodium with platinum were afterwards used, having an E.M.F. above 500°C. given by $E = -174 + 7{\cdot}6075\,T - 0{\cdot}00167T^2$, where T is the temperature Centigrade. The junctions were rolled down to five or six ten-thousandths of an inch thickness and inserted at a depth of $\frac{1}{2}$ in. from the cylinder wall. These couples were able to withstand the highest temperatures near the walls, and they were not melted except during abnormal explosions. Measurements of the cyclical variations showed a variation of E.M.F. lying between 1·56 and 7·83 millivolts with an average cold junction temperature of 30°C. The temperature variation corresponding to these values ranges between 250°C. and 1,700°C. In estimating the highest temperature reached, the upper limit of temperature is indicated by the partial melting of one of the wires when the engine ran above its full normal load, and the lower limit is indicated by the melting of platinum wire. The melting-point of platinum is $1{,}710 \pm 5$°C., and, in the absence of definite values of the melting-points of the alloys used, it is assumed that both are below the melting-point of iridium for which Violle's value is 1,950°C. The probable causes of error in the measurements were discussed, and the conclusion was reached that the temperature at the place of measurement had a maximum value between 1,850° and 1,900°C.

In the course of a demonstration of vacuum-tight seals between iron and glass, in Section A, Dr. Henry J. S. Sand showed some cathode-ray tubes in which a vacuum-tight seal between iron and glass had been obtained as follows: An iron wire was sealed into a glass tube, and while the glass was hot a small piece of heated steel tube surrounding the wire was pushed a few millimetres into the glass. After cooling, the tube was soldered to the wire. The vacuum-tight seal was produced between the inner surface of the elastic steel tube, which on cooling was put under tension, and the glass which came under compression. Seals with wires of 1 mm. diameter had been produced in this way.

Tuesday, September 6th.

Section A commenced this morning with a discussion on Atmospheric Electricity, opened by Dr. Charles Chree. As a preliminary, Dr. Chree set forth several headings which he thought were suitable for discussion, but confined himself to only two or three of these. He was more particularly concerned with the measurement of potential gradient, which was nearly always positive, the only exception occurring in bad weather, when it became negative. Relative measurement of potential gradient was a comparatively easy matter, but

Digitized by Google

absolute measurement was a much more serious problem. The variations of potential during any one day were very irregular, but if a number of days were considered together then a smooth curve was obtained. Each daily curve could be split up into a variation extending over 24 hours, two over 12 hours, and if necessary others over 12, 8, 6 or any sub-multiple of 24 hours. It was found that the 24-hour curve varied most in mid-winter, while the 12-hour curve had maximum variation in mid-summer. Moreover, the 24-hour curve varied in phase to the extent of eight or nine hours, according to the time of year. Potential measurements taken on the earth were very unreliable, because of the effect of surrounding objects; also measurements taken by the aid of kites or balloons were unsatisfactory because it was impossible to ensure that even two consecutive readings should be taken at exactly the same spot, and again the results were affected by the proximity of the kite or balloon. The latter objection applied equally when the measurements were made on a mountain, but the mountain did at least stand still. It was found that the phase angle depended very much on the altitude. For instance, the mid-winter phase as obtained at the top of the Eiffel Tower was the same as the mid-summer phase obtained on the ground below. There was no well-marked 11-year period in atmospheric electrical conditions as was the case with terrestrial magnetism. In fine weather the potential gradient was probably about 200 volts per metre, but in bad weather it was much higher, readings as high as 1,000 volts per metre having been obtained in the presence of fog. At Potsdam the records showed 2,000 volts per metre, and it was quite possible that with improved apparatus they might be able to obtain results very greatly in excess of the existing ones. He suggested that the potential gradient might have a very important bearing on the growth of vegetation. For example, a tree was electrically connected with earth and its leaves would therefore be at zero potential, but if it were only 10 metres high the potential in the immediate neighbourhood of the leaves would be something like 2,000 volts under ordinary conditions. In connection with thunderstorms, he had never understood why it was that some trees were struck so much more frequently than others; the oak seemed particularly unfortunate, while the beech was hardly ever struck. If people must get under trees during a storm then they should select beech in preference to oak, and then not stand under an isolated tree, but go right into the middle of a wood. If he were caught by a storm while playing golf he would lie down in a bunker! In experiments on atmospheric electricity the gradual loss of charge from an insulated body was a source of great trouble, the rate of loss being much higher with a negative charge than with a positive. At Kew it was very high. From determinations with Wilson's apparatus for measuring "earth-air" currents it was ascertained that the average current in fine weather was about 2×10^{-12} amp. per square centimetre, and was always in the same direction, except in bad weather. As to whether it was a flow of positive electricity from the air to earth, or a flow of negative electricity from earth to air was a matter of opinion, but he inclined to the latter view. The question arose as to where all the electricity came from, and various unsatisfactory theories had been propounded. It was suggested by some people that the electricity went up at places of fine weather and came down at the same time at places of bad weather. This, however, could not account for the phenomenon, because it was known that the rain brought down much more positive than negative electricity. He put forward the suggestion that the radio-activity of the earth might account for it, for it had been shown that air drawn from the earth was highly radio-active. Hence, air might be forced into the earth under the influence of a high barometer and drawn out again when the barometer fell. This view was supported by the fact that the variations of the electrical conditions of the atmosphere corresponded to a certain degree with the variation of the barometer. As an illustration of the enormous penetrative power of atmospheric electricity, he quoted the case of a charged electroscope enclosed within an insulating vessel whose walls were sufficiently thick to prevent the passage of X-rays. In spite of this, the charge was gradually dissipated. He concluded by remarking that extremely practical results of investigation on atmospheric electricity might be expected in the near future.

In the course of his remarks, Sir Oliver Lodge said it must be borne in mind that the 24-hour curve might well be affected by the particles which the earth would pick up between the hours of 6 a.m. and 6 p.m. He had always wondered whether the change in the atmospheric electrification was the cause or the effect of bad weather. In other words, did the change in the potential bring about rain or did the rain bring about the potential change? If he were a capitalist he would try the experiment of controlling, or at all events modifying, the weather by varying the atmospheric electrification artificially. Of course, it would have to be done on a large scale and would involve large expenditure, but if successful would be well worth the money. On the whole there was too much drought on the earth, and it would be a great achievement to induce rain to fall where wanted. Referring to the effects of electricity on vegetation, he thought there could be no doubt that under certain conditions it had a stimulating effect. Explorers stated that plants grew with great rapidity in the Arctic regions, although they received so little sunshine, and he thought this was due to some electrical cause.

There was every reason to think that, for some forms of vegetation, electrical stimuli had the same effect as sunshine, and induced more vigorous growth. Moreover, experience showed that positive electricity, which alone produced this effect, should not be supplied in bright, dry weather, but only when it was dull and rainy. He personally knew of a farmer who increased his crops by 30 per cent. by the use of positive electricity, but on one occasion the crop was less than normal. It was discovered on investigation that for that particular year negative electricity had been supplied. The fact was that the apparatus was very simple and had been worked by a farm hand who, however, had managed to get things muddled up. Another farmer of his acquaintance had tried the treatment on a crop of beans, but the result was disappointing and he could not be induced to repeat the experiment. The fact was, he (Sir Oliver) thought that electricity appeared to damage leguminous crops. He thought that the points and edges of leaves facilitated the discharge of electricity from plants. This it was known, took place freely under the influence of ultra-violet light.

The next speaker was Dr. W. N. Shaw, who expressed disagreement with Sir Oliver Lodge regarding the control of the weather. He would like to know whether Sir Oliver realised the amount of energy represented by an inch of rainfall. In order to produce or abstract this energy something colossal would be needed. He suggested laboratory experiments first. He knew that some time ago Sir Oliver Lodge had conducted experiments in which clouds were represented by tea trays, but the fact was that there was nothing resembling a tea tray moving about in the atmosphere. Could not some closer approximation be obtained?

The next Paper of electrical interest was on "Photoelectric Fatigue," by Dr. H. Stanley Allen, and this was followed by one on "The Recoil of Radium B from Radium A," by Messrs. W. Makower, S. Russ and E. J. Evans.

In Section B (Chemistry) a report on "Electro-Analysis" was presented. This will be found in another column.

The Papers read before Section G were exceedingly good. That by Prof. S. P. Thompson on the "Laws of Electro-Mechanics" we hope to give in abstract next week. Dr. Thompson has collected together the expressions employed so frequently in electro-magnetic calculations and set them forth in his inimitable style. His exposition of the work was extremely clear, and he was particularly careful to point out that the symbol S does not always stand for number of turns, but may, in certain more complicated cases, include linkages, which, in simple cases are, of course, numerically equal to turns.

Mr. Frederic Bacon's Paper on "The Testing of Heat-Insulating Materials" was excellent; an abstract of it will appear in our next issue.

Digitized by Google

In another column there appears the Paper read by Prof. E. Wilson and Mr. W. H. Wilson on "A New Method of Producing High-Tension Electrical Discharges," and it is necessary to refer only very briefly to it here. The fundamental is, of course, a spark coil, but it is by no means an ordinary spark coil. For instance, a 10 in. coil looks like an ordinary 3 in. coil and weighs only 10 lb. The primary of the coil is connected in series with an inductance and in parallel with them is a condenser. Attached to a small motor is a mercury contact maker with three contacts. The action is as follows: the mercury break is in such a position that the primary coil and the inductance are connected across the mains, as is also the condenser. This enables a magnetic field to be built up in the two coils and for the condenser to be charged. On the break being slightly rotated the supply is cut off, and the inductance discharges, as it were, into the condenser, raising its charge to a still higher potential. At the very instant that this discharge is completed the connections are changed, so that the inductance is cut out and the condenser connected directly to the primary of the coil, when a high frequency oscillatory discharge follows. Among the advantages claimed for this apparatus are: (1) It will work equally well on high or low tension circuits, whether alternating or continuous current. (2) It is extremely portable, weighing less than one-fourth of the ordinary coil and break. (3) The inverse E.M.F. is entirely eliminated, thus making it very suitable for X-ray work. (4) The efficiency is very high on account of small C^2R losses. (5) The resistance of the secondary is low (for a 10 in. coil about 3,000 ohms only), thus making it very suitable for wireless telegraphy. A feature of interest is the core, which is made of very fine insulated soft iron wire; this is absolutely necessary, owing to the high frequency of the discharge around the primary coil. The secondary coil is composed of fine aluminium strip, each section being one strip in width. The core of the inductance is not laminated as it is impossible for serious hysteresis losses to occur there owing to the slow rate of charge and discharge.

The Association will meet next year at Portsmouth under the presidency of Sir William Ramsay, K.C.B., F.R.S. The meeting in 1912 is to be held at Dundee, while an invitation to visit Australia has been accepted for 1914.

CORRESPONDENCE.

THEORY OF THE QUADRANT ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The point raised by Prof. Robertson, and reiterated in his letter of September 2nd, with regard to absolute potentials occurring in electrometer formulæ, is one that will certainly demand attention when once an example of a formula containing absolute potentials is found. The veriest schoolboy knows that in electrostatic problems the potentials are represented as differences relatively to that of some one body taken as a standard of reference, and that all the actions depend on these differences. In the electrometer it may or may not be more convenient or more rational to take the needle as the standard instead of the case; but, in any event, the symbols employed represent P.D.s, not absolute potentials.

As to the second point on which he insists—namely, the impossibility of resolving the total electrostatic couple into deflecting and controlling components—I have only to explain that the type of electrometer which I had in mind when writing my Paper was the ordinary reflecting instrument working over a restricted range about a fixed zero. In such an instrument, charged to fixed potentials, the total electrostatic couple on the needle, when plotted against the displacement θ, gives a curve the part of which lying within the working range may usually be taken as a straight line, and may therefore be represented by $A+B\theta$. There is sufficient experimental evidence to render unnecessary any argument (if argument be needed) as to the correctness of this. The quantities A and B which determine the deflecting and controlling components of the electrostatic couple will, of course, depend on the potentials, the shape of the needle, &c.; but this in no way alters the fact that, for a given electrometer system under given potentials, and working about a fixed zero, the total electrostatic couple can be resolved into components in the manner described, provided always the deflections are not too large. Some misconception as to the restrictions which I impose probably accounts for any misunderstanding that may have arisen.

So far as mere algebra is concerned, I have no quarrel to pick with Prof. Robertson's formula; but it is essentially wrong in form, because V_1 is missing from that part of the denominator which does not contain k, that is, from the part which represents what I call the electrostatic control. This, on the face of it, by considering the pure physics of the problem alone, is incorrect. Prof. Robertson will see that this is so by introducing into his final formula the instrumental conditions, say, for example, the conditions for symmetry, the simplest assumptions as to which are that $dc_1/d\theta = a - b\theta$ and $dc_2/d\theta = a + b\theta$ numerically. He will then find that he has terms containing θ in the numerator, necessitating the re-casting of his formula, which ultimately takes the form given in my last letter.

It would be quite easy to frame any number of formulæ like that of Prof. Robertson containing any function of V_1 and V_2 juggled artificially into the denominator, all equally correct algebraically and all equally wrong physically. Any one of these might be set forth to masquerade as an electrometer formula with no real credentials whatever to substantiate its claims, and might easily lead the unwary to believe that the electrostatic control could be the most weird function of V_1 and V_2, or no function at all, for the matter of that. Any collection of algebraic symbols evolved to represent a physical relationship must always be submitted to the test of physical rationality, or common sense. Thus, the denominator of a correct electrometer formula must contain neither more nor less than what refers to the control, and the electrostatic part of the control must be a function of V, V_1 and V_2. Submitted to this test, both the formulæ of Prof. Robertson—the one containing $dc_2/d\theta$ in the numerator and V_1 only in the denominator, the other containing $dc_1/d\theta$ in the numerator and V_2 only in the denominator—while algebraically rational, are seen to be physically irrational. The formula obtained by combining them—that is, the formula suggested by me containing $(dc_1/d\theta + dc_2/d\theta)$ in the numerator and terms containing $(V-V_1)$ and $(V-V_2)$ in the denominator—is the correct one, being physically as well as algebraically rational.

What has just been said applies more particularly to a symmetrical electrometer, my remarks being perforce confined to this case because Prof. Robertson's manipulation of his formula, so as to get the factor $(V_2-V_1)(V-\frac{1}{2}\overline{V_1+V_2})$ into the numerator, shows that he has this special case in mind. If he has not, then he has no right to drag this factor into the problem because no such factor occurs in the final formula for an unsymmetrical electrometer. Efforts of this kind to twist, by algebraic artifices, an equation prematurely into some preconceived form, essentially foreign, very probably, to its true and ultimate character, are strongly to be deprecated; they are necessarily based on pure guesswork and are therefore pretty well bound to lead to results that are physically incongruous, if not actually erroneous. The only safeguard against hasty generalisation of this nature is to incorporate the instrumental conditions, when the desired formula will emerge at once in its proper form without the necessity of an appeal to the arts of algebraic subterfuge. Till these conditions are introduced the formula is, strictly speaking, not an electrometer formula at all, and any attempt to predict its final form, or to determine what particular functions of the variables enter into the numerator and denominator, must be very largely a matter of speculation. The necessary instrumental conditions here alluded to can be expressed approximately in Prof. Robertson's notation by putting $dc_1/d\theta = a_1 + b_1\theta$ and $dc_2/d\theta = a_2 + b_2\theta$; or, what is equivalent but preferable, by writing the total electrostatic couple in the form $A+B\theta$. Unless these precise conditions can be assumed, the resulting

Digitized by Google

electrometer formula is much too complicated to be of any practical value. The possibility of framing a practically useful electrometer formula thus involves the possibility of representing the total electrostatic couple over the working range by an expression $A+B\theta$; in other words, it involves the possibility of regarding the electrostatic couple as resolvable into a fixed component and a component proportional to the deflection. If Prof. Robertson admits the feasibility of the one he must needs concede the possibility of the other.

Prof. Robertson says that the only difference between us is that I use a K while he expresses what K denotes in terms of a well-known physical quantity. The difference between us is that I do not introduce an entirely unnecessary quantity—namely, the capacity. My Paper was written to illustrate this particular point, and in it I nowhere even mention capacity. By the use of the electrostatic forces, expressed as such and not in terms of an extraneous quantity, I am able to account for the characteristic properties of the electrometer, as usually employed, in a way so simple as to verge on the obvious. The method even lends itself to a purely verbal explanation, without the aid of a single algebraic symbol, a claim which could scarcely be put forward for methods involving capacity. The introduction of capacity means obscuring the mental picture, and thus leads to confusion of thought, as witness the history of the electrometer theory. The correct explanation of the peculiarity in the electrometer characteristics has taken so long to arrive at, and has involved so many mathematical disquisitions, mainly because Maxwell in the first instance adopted the capacity method, and in dealing with a symmetrical electrometer said: I can assume as a first approximation that the capacities on the two sides of the needle can be represented by $a-b\theta$ and $a+b\theta$ respectively. If he had said: The electrostatic forces on the two sides of the needle vary linearly and can be represented by $a-b\vartheta$ and $a+b\theta$, the well-known characteristics would have been revealed at once, and much experimental work, together with reams of algebraical scribbling, rendered unnecessary.—I am, &c.,

Manchester University, Sept. 3. ROBERT BEATTIE.

RESTRICTED HOUR SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At Burton-upon-Trent we have been specially pushing the sale of power on the Restricted Hour System, as you are aware, and you have from time to time kindly emphasised this matter in your columns. I think the following figures, which are extracted from an article I have contributed recently to the "Electrical Review," will be of interest to your readers in this connection.

Figures showing Effect of Restricted Hour System.

	Previous to introduction of Restricted Hour System.			After introduction of Restricted Hour System.			
Year ended March 31st....	1903-4.	1904-5.	1905-6.	1906-7*	1907-8.	1908-9.	1909-10
Lighting units sold	278,289	292,602	313,254	311,899	336,805	318,319	301,964
Motor ditto	36,904	74,806	103,100	260,601	412,384	548,549	560,604
Total of above ...	315,193	367,408	416,354	572,500	749,189	866,868	862,568
Motors connected during year, kw.	11·5	44·0	62·5	169	190	62·0	102·8
Lighting connected during year, kw.	48·0	100·0	86·0	41	47	68·0	30·6
Total motors and lighting connected during year, kw.	59·5	144·0	148·5	210	237	130	133·4
Max. load, kw....	370	427	492	511	515	504	500
Load factor for lighting and motor supply...	9·73%	9·84%	9·67%	12·7%	16·6%	19·6%	19·7%

From the above it will be seen that for the 3½ years the restricted hour system of power supply has been in operation the total additional power and lighting connections amount to 710·4 kw., or an increase of 60 per cent., while the maximum load on the station has remained practically constant. This has had the effect of raising the load factor from 9·67 per cent. for the year ended March, 1906, to 19·6 per cent. in the year ended March, 1909, or an improvement of over 100 per cent. in three years.—I am, &c.,

Electricity and Tramways Department, P. J. PRINGLE.
Burton-upon-Trent, Sept. 3.

* Restricted hour system commenced at the end of October, 1906.

REPORT OF THE BRITISH ASSOCIATION COMMITTEE ON ELECTRO-ANALYSIS.*

The work on electro-analysis has been further elaborated during the year by the publication of Papers on the "Electro-deposition of Metals," by Dr. F. Mollwo Perkin and W. E. Hughes,† and by Dr. H. J. S. Sand on "Apparatus for the Rapid Electro-analytical Separation of Metals,"‡ and "The Electro-determination of Lead as Peroxide."§

Perkin and Hughes have devised and experimented with new cathodes for the rapid deposition of metals. One simple, smooth cathode is in the form of an elongated thimble, and with this, when rapidly rotated, very smooth and even deposits can be obtained; the total active electrode surface is about 16.3 sq. cm. Extended work has shown, however, that a platinum gauze cathode surrounding a spiral anode, which is rapidly rotated, gives the most satisfactory results. For separation of metals by means of graded potentials a funnel-shaped vessel with a tap for running off the electrolyte is used. This vessel has a side tube fused into it at about the centre to take the capillary of the auxiliary electrode. This form of apparatus gave very good results, and is very simple in working.

The experiments referred to a year ago by Dr. Sand with an anode made partly of glass and a cathode of metals, other than platinum, have been completed by him, and will be published shortly. Satisfactory results for copper were obtained with a cathode of silver, and for zinc with a cathode of nickel. In the former case the electrolyte deposit may be removed from the electrode by a solution of hydrogen peroxide in diluted sulphuric acid.

Experiments on the separation of the four metals—copper, antimony, tin and lead—have been continued. In connection with this work it has been shown that chlorides exert a retarding influence on the deposition of copper. This is due to the formation of derivatives of cuprous chloride during electrolysis from which copper is only deposited at a high potential. The conditions for the separation of copper from antimony have been fully elaborated, and mixtures of the three metals—copper, antimony and tin—corresponding to industrial alloys have been successfully analysed. When lead is present in small quantity this may be deposited with the tin; the greater part of the tin may afterwards be removed by making the electrode the anode in a solution containing sodium polysulphides. The lead may then be separated from the small quantity of remaining tin by means of nitric acid, and can afterwards be deposited electrolytically.‖

* This report was presented at Sheffield. The Committee consists of Prof. F. S. Kipping (Chairman), Dr. F. M. Perkin (Secretary), Dr. G. T. Beilby, Dr. T. M. Lowry, Prof. W. J. Pope and Dr. H. J. S. Sand.

GALVANOMETER FOR ALTERNATE-CURRENT CIRCUITS.¶

BY W. E. SUMPNER, D.SC., AND W. C. S. PHILLIPS, B.SC.

Summary.—The authors describe a galvanometer for alternating-current circuits and resembling a moving coil galvanometer in almost every respect except that its field is due to a laminated electromagnet excited by an alternating voltage. A specially shaped stamping is placed between the poles. The use of the instrument as a voltmeter and for comparing inductances and capacities is explained.

The steady E.M.F.s and highly sensitive galvanometers available for use with direct-current tests render such tests excellent whether deflectional or balance methods are in question. Tests involving change of current, such as induction measurements, are not so satis-

¶ Abstract of a Paper read before the Physical Society. A brief account of the discussion that followed the reading of this Paper and a view of the instrument described appeared in THE ELECTRICIAN, June 24, 1910, p. 433

Digitized by Google

factory. In ballistic tests the best galvanometers are in many cases not sensitive enough, and though balance methods are available they are usually not so simple in working as those in which steady currents are employed. Alternate-current tests are still less satisfactory. It is impossible to generate an E.M.F. whose constancy is comparable with that of a battery or accumulator. Special difficulties arise owing to effects of frequency, wave-form and phase. Balance methods can be devised, but they are rarely of much use, owing to the above difficulties and to the absence of sensitive instruments. A distinct advance has been made during the last few years by the construction of improved forms of vibration galvanometer. But this instrument overcomes only some of the difficulties. It is a sensitive indicator rather than a measuring instrument. It must be adjusted to resonance for the best effects, and its sensitiveness is necessarily affected by slight changes in current frequency.

The sensitiveness of ballistic galvanometer tests can be greatly increased by the use of mechanical commutators such as the secohmmeter of Ayrton and Perry, or subsequent modifications of this by Fleming and Lyle. But such methods only make use of a crude form of alternate current, and it appears that the simplest and most effective cumulative method for testing effects due to changes of current must in the end prove to be one involving the use of alternate currents generated in the ordinary way. The construction of the indicating instrument constitutes the real obstacle. The reflecting instrument for alternate-current circuits described in this Paper is the result of an attempt to overcome this difficulty. The instrument is like a moving coil galvanometer in almost every respect, except that its field is due to an electromagnet excited by an alternating voltage. The theory of non-reflecting instruments of the same type has already been fully explained,* but it may be convenient to refer briefly to it.

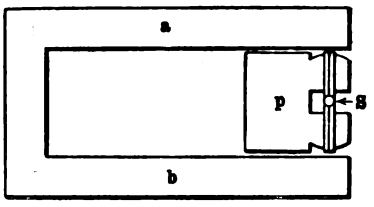
If an alternating voltage, V, be applied to an electromagnet whose winding consists of m turns, the core flux N will be such that $V = rA + m\dot{N}$, where r is the resistance of the coil and A the current traversing it. If the coil and electromagnet be so designed that for currents of the frequencies used the resistance is negligible in comparison with the impedance, we can neglect the term rA. It follows that the rate of change of N will be at each instant a measure of V, and this will be true whatever the permeability or hysteresis of the core. We thus have a magnet whose strength is accurately determined by the applied voltage whatever the physical properties of the core. Such an electromagnet can easily be made very strong. Moreover, the shorter the air-gap between the poles is made, the denser is the magnetic flux due to a given current and the greater is the ratio of impedance to resistance for a given winding. Thus the stronger the electromagnet is made by improving its magnetic circuit, the more accurate it becomes, provided this electromagnet is excited by the voltage of the circuit.

The instrument described has a laminated electromagnet formed of stampings shaped as shown herewith. These stampings are of two kinds—a rectangular portion with two straight limbs, *a b*, forming the core of the electromagnet, and a specially shaped stamping, *p*, between the poles. The stamping *p* is separated from the magnet limbs on each side by an air-gap. Each gap consists of two portions, a narrow part about 1 mm. across bounded by the straight edges of *p*, and a wider portion in which one of the vertical sides of the moving coil can turn round the curved edges of *p*. The moving coil, of 50 turns, is similar in shape, suspension and mode of control to that of an ordinary permanent magnet instrument. It has a central spindle indicated at *s* and working in a recess suitably stamped in *p*. The pile of stampings is about 4 cm. deep and 9 cm. long, the limbs being 1 cm. wide. Each of the limbs *a b* is wound with a coil of 2,000 turns of fine wire, and also with a coil of 100 turns of thicker wire. The two fine-wire coils are put in series and connected to three terminals; the two thicker coils are also put in series and joined up to two additional terminals. Thus the instrument can be excited by a winding consisting of either 200, 2,000 or 4,000 turns, according to the voltage used. The iron is not too strongly magnetised if the winding used contains 20 turns per volt on 50-cycle circuits. Thus 200 volts may be applied to the 4,000-turn coil, or 10 volts to the 200-turn coil. But the instrument is so sensitive that such excitation will only be needed for exceptional tests. The moving coil may be used with a condenser or other apparatus, either on some special circuit or in conjunction with one or other of the field coil windings. The instrument has been constructed by Robt. W. Paul, to whom several of the working details are due. The following are some of the uses of the apparatus:—

Use as a Voltmeter.—If a voltage, V, be applied to a field coil of m turns and if another voltage V_1 be applied through a condenser of K mfd. to the moving coil, it can be shown that the torque acting on the moving coil is a measure of $\frac{1}{m}KV\bar{V}_1$, or of the mean product of the two voltages. If the condenser voltage is obtained from one of the field coils of n turns the torque is measured by $Kn(V/m)^2$. There is really another factor the value of which would not be quite constant if the induction density in the gap varied with the position of the moving coil. But in the present instrument this factor is essentially constant owing partly to the shape of gap adopted and partly to the fact that for a reflecting instrument the movement of the coil is very slight. Numerous tests have shown that for any given choice of coils and condenser, the scale deflection is strictly proportional to the square of the applied voltage quite up to the limits of the scale used (300 mm. each side of zero for a scale distance of 1 metre). The numbers denoted by m and n may each be chosen either 200, 2,000 or 4,000, while the capacity K may be given widely different values. It is thus clear that the instrument can be used as a voltmeter for a large number of ranges.

The deflection is independent of frequency and wave-form if the field winding to which the voltage is applied has a resistance negligible in comparison with its impedance. This will always be the case if the frequencies used are high. But if the frequency is low and the mass of copper used in the magnetising coil is small, the resistance of this coil will become comparable with its impedance, and the deflection will then be dependent on frequency.

Use with Null Methods.—In ordinary bridge methods (of which the author illustrates six) for comparing inductances and capacities a ballistic galvanometer is used as an indicator, and to test the balance the current A through the arms of the bridge is made or broken by a key. All these methods may be used with the present instrument for steady inductive balances on alternate-current circuits, and the same formulæ apply to the zero deflection condition, provided (ii.) the alternate voltage V applied to the field-coil of the instrument also causes the current A through the bridge conductors; (ii.) the alternate current A is made essentially cophasal with V by



the use of suitable non-inductive resistances; (iii.) the moving coil of the instrument is placed directly across the bridge (using a reversing key when desirable). It results from the special properties of the instrument that the flux in the gap of the electromagnet is in quadrature with the applied voltage (and thus in quadrature with A). The inductances or capacities produce voltages or currents also in quadrature with A, and thus in phase with the flux, so that their phase is such that they produce the maximum torque of the moving system.

These methods have all been thoroughly tested on alternate-current circuits with the present instrument, and with most satisfactory results. The balance can be adjusted with ease to 1 part in 10,000, when the voltages set up on the coils or condensers are merely of the order of 1 volt, and thus suitable for use with the resistance boxes ordinarily found in laboratories. Certain special points, however, call for notice. When a balance of great precision is needed, the minute E.M.F. (e) induced in the moving coil by the alternating field of the magnet tends to cause a small deflection disturbing the balance. When the moving coil circuit is essentially non-inductive the current due to e will be in phase with e, and in quadrature with the flux, and in such cases the corresponding deflection will in general be negligible. For inductive circuits, however, a small deflection due to e will occur. But in all cases any effect due to e can be accurately eliminated by using a false zero method—that is, by adjusting the balance till the reading on the scale is unaltered by switching the bridge current on or off. In most cases it will be found sufficiently accurate to take the mean of the two conditions of balance obtained by using a reversing key with the moving coil. The false zero method is simpler and is mathematically accurate, though in practice, as with all false zero methods, there is a liability to a small error due to the variations of the false zero deflection in sympathy with fluctuations in the main current or voltage.

Examples of the bridge methods are given by the authors to illustrate the conditions of working.

Other Uses of the Instrument.—The voltmeter tests described show that the instrument can be used to measure very small capacities,

* "Proc. Roy. Soc.," Vol. LXXX. (1908), "Alternate-current Measurement."

Digitized by Google

especially in cases where it is possible to apply high voltages to the condenser. It will be apparent from the expression $\frac{1}{m} K\bar{V}\bar{V}_1$ that if the voltage V_1 applied to the condenser is in phase with the voltage V applied to the field, and a known multiple of it, the sensitiveness can be indefinitely increased by making V_1 large.

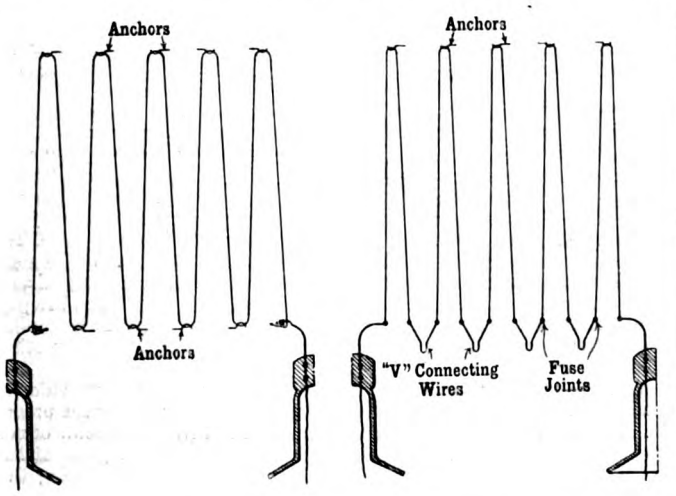
The instrument has not yet been tested with alternate currents of higher frequencies than 100 cycles per second, but there appears no reason to suppose there will be any difficulty in the way of its use for high frequency work.

Added July, 1910.—Mr. A. Campbell has drawn our attention to a Paper, previously unknown to us, in which Stroud and Oates ("Phil. Mag.," 1903) describe an instrument resembling in some respects the galvanometer here referred to. The Paper gives data of the electromagnet showing that it contained a greater volume of iron than that of the instrument here described. But no details are given of the air-gap between the poles, and it does not appear that any attempt was made to produce a magnetic field whose phase is essentially in quadrature with that of the applied voltage. The characteristics of the present instrument are the result of such a relationship. In the Stroud galvanometer the field in the gap is probably stronger and less uniform than that of the instrument here described, since the disturbing influence of this field on the moving systems seems much more serious.

A NEW FORM OF TUNGSTEN LAMP.*

BY C. F. SCOTT.

The author describes a tungsten lamp called the "wire type," which has been developed by the engineers of the Westinghouse Lamp Co. The accompanying illustrations compare the wire type



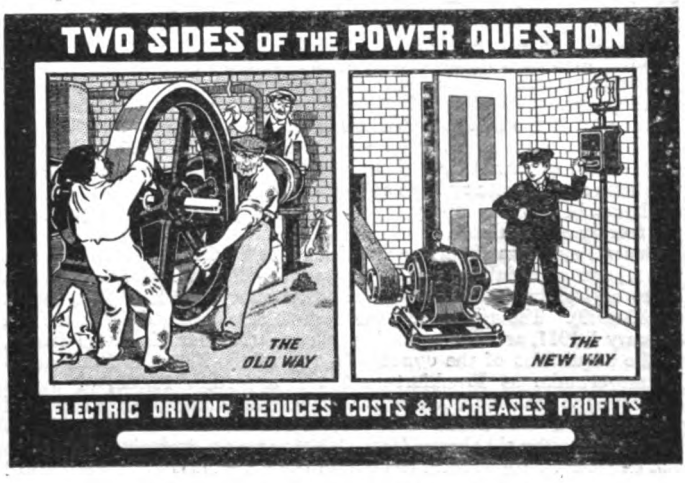
with the usual type of tungsten lamp. The main elements of the former are a single long filament, intermediate hook supports which hold the filament loosely and a terminal which is described as mechanically and electrically adequate. The common tungsten lamp consists of a number of filaments in series, the individual filaments having their ends fused together to stiff supporting wires. The new lamp adopts what is described as the ideal way of overcoming the disadvantages of this method, namely, by employing a single filament and so mounting it that the filament is not rigidly fastened to supports. The single filament is wound back and forth around hook supports at numerous points, and a few turns near each end wound in the form of a spiral spring around the respective leading-in wires, and the ends fused. The several turns of the filament around the leading-in wires act as a sort of a spring, so that a slight bending of the filament, resulting from a blow or vibration, does not act directly upon the fused joint, as would be the case if the straight part of the filament came directly from the fused joint as in ordinary construction. Furthermore, carelessness in the act of fusing is stated to be of minor consequence in the wire type of lamp, whereas it might seriously lessen the strength of the filament in the common forms of lamp.

A tungsten lamp, using, say, five filaments, is analogous to five independent lamps in series, and its life will be fixed by that of the weakest filament. On the other hand, a process in which a yard or more of filament is made in one piece is not liable to the conditions which are possible and probable when a lamp contains several filaments which have been made at different times and under the necessarily different conditions incident to commercial manufacture. It is stated that the mechanical excellence of the new lamp is attested by the result of comparative experiments with such lamps and lamps of the ordinary type. Among these was a test consisting in dropping a weight on a board held on supports about 4 ft. apart, to which lamp sockets were attached. It was found that with the wire type the weight had to fall from four times the height to cause the same destruction as in the case of the fused type of lamp. The mechanical tests in the aggregate showed that the wire type of lamp is much less liable to injury than the fused type where subjected to blows which are of a kind similar to those that may be expected in service. It is stated that the wire type tungsten filament is made in long lengths, the present equipment making several miles a day.

* Abstract from "The Electrical World" of a Paper read before the National Electric Light Association.

ELECTRICITY SUPPLY PUBLICITY.

The efforts of the Committee of Electric Supply Publicity to popularise the use of electrical methods have largely consisted of a number of well-designed posters and postals, the latter taking the



TWO EXAMPLES OF SUPPLY PUBLICITY POSTERS.

form of postcards, booklets, leaflets, &c. We have, from time to time, illustrated some of the best of these designs, and the accompanying illustrations show two of the latest examples which this class of publicity has provided. It will be noted that Sarah Anne, as might be expected, offers no objection to the easier times which electric heating gives her in the round of her daily work. If the

Digitized by Google

electric radiator is brought into the domestic circle many of the discomforts and much of the work which coal fires entail will be avoided, and now is the time to push this side of the electricity question. The smaller illustration is a modification of an earlier poster issued by the Committee, and provides the user of small power units an object lesson. The aspect here shown of electricity supply cannot be driven home too severely. The industrial who uses the small steam, gas or petrol engine when electric current is available at a reasonable rate has only himself to thank for the trouble he finds for himself; those who know most about the subject will appreciate the pictorial way of putting it.

The present opportunity may be taken for pointing out that the Publicity Committee has recently extended its scope of usefulness to cover the provinces and a portion of the title ("London and District") is now omitted. The option of purchasing the literature issued by the Committee has also been extended to the Colonies.

GERMAN ELECTRICAL MANUFACTURERS COMBINATION.

It is officially announced that the Allgemeine Elektricitäts Gesellschaft have acquired the dynamo works (at Frankfort) of the Felten & Guilleaume-Lahmeyerwerke A.-G.

In this connection it is stated that, owing to the reduction of the dividend for 1909 of the Felten & Guilleaume Lahmeyerwerke, which was due to the slackness affecting the dynamo factory at Frankfort, negotiations were opened for the disposal of the Frankfort factory. These negotiations have now resulted in an understanding with the A.E.G., in virtue of which the Felten & Guilleaume Co. disposes of the dynamo factory to the A.E.G. in return for an issue of A.E.G. shares. The factory is to be transferred to the A.E.G. in the form of a company with a share capital of 10,000,000 marks (£500,000) and reserves of 3,000,000 marks (£150,000). The new company takes over the buildings and plant of the dynamo factory, together with inventory and stores, but not the debit and credit accounts.

The official narrative continues as follows: "The factory thus falls into the hands of an undertaking that possesses the strength and resources necessary for its profitable development. At the same time the A.E.G., in consequence of the relation established through the transfer of its shares, will be able to enter the Frankfort factory on its balance-sheet at a low book value, while the Felten & Guilleaume Co. will reap the advantage that it will for the future be able to invest with profit in its main works the considerable amount of capital that it has hitherto expended on its Frankfort factory. Its former position is considerably improved, as it can now, instead of incurring losses on its dynamo factory, effecting profits by means of the capital which is now released. The A.E.G. has (it is stated) only consented to take over the dynamo factory under the provision that a sufficient amount of shares of the Felten & Guilleaume Co. is made over to it on favourable terms. Certain far-seeing large shareholders of the Felten & Guilleaume Co. transfer 16,000,000 marks (£800,000) of shares to the A.E.G., and the latter (jointly with the Electro Bank of Zürich allied with it) acquires 32,000,000 marks (£1,600,000) of shares of the total 55,000,000 marks (£2,750,000) of shares of the Felten & Guilleaume Co. and therewith the controlling influence over this highly reputable company, from whose signature the name of Lahmeyer will henceforth be withdrawn. The advantages derived by the A.E.G. are increased by the fact that by taking over the Frankfort dynamo factory it disposes of certain competition, and acquires with the dynamo factory both material values and goodwill on favourable terms. While the A.E.G. thus considerably strengthens its position, the combination will pave the way to renewed successful efforts on the part of the Felten & Guilleaume Co. by releasing it from the care of the Frankfort works. The transactions require 20,000,000 marks (£1,000,000) of new A.E.G. shares, and at the same time shareholders will have a preference right to subscribe for 10,000,000 marks (£500,000) of shares, in order to supply funds for the working and development of the factory at Frankfort.

General meetings of both companies are called for October 13th, when the following resolutions will be proposed:—"The A.E.G. shall raise its share capital by 30,000,000 marks (£1,500,000) to 130,000,000 marks (£6,500,000). The new shares, which shall have dividend rights as from January 1, 1911, are to be applied as follows: One-third, in round figures, to the acquisition of the dynamo factory of the Felten & Guilleaume-Lahmeyerwerke at Frankfort-on-Main; a further 10,000,000 marks (£500,000) to the acquisition of 16,000,000 marks (£800,000) of shares of the Felten & Guilleaume Co.; 10,000,000 marks (£200,000) will be made over to the old shareholders at 210 per cent., inclusive of all costs and expenses. The general meeting of the Felten & Guilleaume Co. will pass resolutions to convert the Frankfort factory into an independent company, with 10,000,000 marks (£500,000) capital and 3,000,000 marks (£150,000) reserves, the transfer of these shares to the A.E.G. and the change in the name of the Mülheim undertaking into the old name of the Felten & Guilleaume Carlswerk A.G.

In order to bind the A.E.G. and the Felten & Guilleaume Companies more closely together, certain directors of the Felten & Guilleaume Co. will be proposed as a supervisory committee (Aufsichtsrät) for the A.E.G., and certain others will be proposed as a supervisory committee for the Felten & Guilleaume Co.

TRANSVAAL ELECTRIC POWER ACT, 1910.

We give below a full abstract of this act, which received assent on April 28, 1910, and constitutes an Advisory Board of not more than five persons (styled the Power Undertaking Board).

By the provisions of the act, the Government mining inspector is to be one of the members and also chairman of the Board, and all the members shall be officers in the railway or public service. No person, except the Council of a municipality, shall (save as hereinafter provided) engage in an undertaking to supply to any other persons power exceeding 20,000,000 units in one year unless the undertaking be licensed, but undertakings existing prior to the commencement of the act may be continued for one year, and no longer, unless licensed under the act. Applications for licences must be sent with plans to the Minister of Mines or other Minister to whom the administration of the act is assigned. Applications from companies must be accompanied by the memorandum and articles of association and particulars of capital, and must state situation and extent of land for sites of generating and distributing stations, names of owners and occupiers of such land, proposed sources of water for the undertaking, area of supply, route of transmission lines, powers required for breaking up roads, &c., proposed schedule of prices to consumers and minimum to be supplied to any consumer, estimated cost of generation, contracts entered into, &c., &c. The Board will fix a date to hear applications and objections, and when an applicant wishes to supply power in the area of a licensee he must give notice to such licensee 21 days before the hearing. Applicants must give notice to the town clerk if it is proposed to construct a transmission line through a municipality or to supply power within a municipality. A licensee may not supply power within a municipality without the consent of the Council thereof, except for mining purposes or to the railway administration or any Government department; but the consent of the Council must not be unreasonably withheld (in the opinion of the Board), and the Governor may in such a case authorise supply without the consent of the Council.

Licences will not be transferable without the consent of the Minister, and the licensee shall not carry on any other business or undertaking, nor in the generation of electric energy use coal from any mine in which he is interested directly or indirectly. The grant of a licence shall not be deemed to confer any monopoly. The Governor may fix a limit to the amount of power to be generated. Seven days' notice must be given to an authority having control of roads, sewers, &c., of intention to break up such roads, sewers, &c., and the licensee must pay to the authority reasonable costs of superintendence of such works. No rights over land which is not proclaimed land or land held under mining title shall be acquired without the consent of the registered owner. Power must be supplied to every person applying for same in the area of supply. In cases of delay or refusal to supply, the Minister may decide whether the licensee shall supply, and may prescribe the charges and conditions, having due regard to the provisions of the following sections of the act. A supply not exceeding 300 kw. shall be given within 6 months of the Minister's decision, 600 kw. 9 months, 1,000 kw. 12 months, 2,000 kw. 15 months, 3,000 kw. 18 months, and exceeding 3,000 kw. within such period as the Minister may determine. No person shall be entitled to a supply for premises having separate supply, unless he has agreed to pay such minimum annual sum as will give a reasonable return on the capital expenditure incurred to meet his possible demand and to cover other standing charges.

A licence may contain a schedule of standard prices and provide for periodic revision of such schedule, and for the sharing of surplus profits as follows: At the end of seven years, and thereafter at intervals of not less than three years, the Minister shall revise the schedule, and at the revision not more than one-half of the reduction effected during the interval in the cost of supplying power shall be applied to a reduction of prices, and provision may be made in a licence for an automatic adjustment of prices at any time consequent upon an alteration of railway rates or other circumstances. The licensee shall pay to his consumers 25 per cent. of the surplus profits, ascertained by deducting from gross revenue the working expenditure, head office and administration expenses, maintenance and such other charges and such interest on share capital and debentures as the licence may provide for. The allowance to be made in respect of any consideration passing to a vendor, promoter or founder shall not exceed 20 per cent. of the share and debenture capital. A licensee may vary his charges either above or below the standard price, with due regard to the amount of power consumed, uniformity or regularity of demand, time during which power is required, expenditure in furnishing the supply, &c. Disputes in regard to price shall be referred to the Minister. No arrangement whereby any charge to a consumer shall be reduced below the standard price shall be valid unless the proposal be submitted to and approved by the Minister, and no advantages, rebates, preferences or privileges shall be granted to any consumer except as provided by the act, or as the Minister may permit.

A licence may be revoked and the Governor may expropriate an undertaking for breach of conditions of licence, and continuance of such breach after a month's notice from the Minister, or if a licensee fails to satisfy the Minister within a period stated in the licence of ability to discharge the obligations imposed, or if the licensee fails to deposit the security required by the licence. The Governor may expropriate an undertaking after 37 years upon two years' notice and upon payment to the licensee of the existing value of lands, buildings, works, machinery, materials and plant, and no addition shall be made for goodwill or for prospective profits. The Governor may also purchase an undertaking on similar terms in the event of a licence being revoked. Any dispute as to the purchase price shall be determined by arbitration.

Digitized by Google

Persons stealing electric current shall be liable to penalties prescribed for theft, and persons unlawfully injuring or interfering with apparatus with intent to cut off the supply of current shall be liable to a fine not exceeding £1,000 or to imprisonment not exceeding 10 years. In proceedings arising out of damage or injury by means of electricity the burden of proving that all due diligence was used by him shall lie upon the defendant.

Meters, fittings, &c., shall not be liable to distress for rent, &c., provided they bear marks indicating the licensee as the actual owner. If any person carry on an undertaking without a licence, or in contravention of the act or the regulations or the terms of any licence, or if any licensee fail to carry out the decision of the Minister, he shall be liable to a penalty of £50 for every day such undertaking be so carried on or such failure continue. Any person desiring to supply to any other person power not exceeding 20,000,000 volts per annum may obtain permission from the Governor. The Governor may from time to time make, alter and rescind regulations consistent with the provisions of the act. Nothing in the act shall affect the provisions of the Irrigation Act, 1908, or the Precious Metals and Base Metals Act, 1908, relative to obtaining and use of water to develop power, or the law for the time being relating to the construction, maintenance and working of telegraphs or telephones by the Post Office or Railway Administration, and save as is otherwise specially provided in this act nothing contained in the act shall be deemed to abrogate or alter any powers, rights, privileges or duties conferred upon any municipal council under any general or special law regulating the powers, rights, duties and privileges of that Council, or to prevent such a Council from carrying on without a licence an undertaking to supply power.

LEGAL INTELLIGENCE.

Feld Bros. & Co. v. Pinkerton.

In the City of London Court last week, before Judge Lumley Smith, K.C., plaintiffs sought to recover £37. 6s. for Osram and other metal filament lamps supplied.

DEFENDANT complained that the Feld lamps supplied to him went black and were returned by his customers. He said that all electric lamps went black after being burned for 1,200 hours.

Mr. FICHTERMANN (of plaintiffs' firm) said defendants had kept the lamps complained of for five months, and that was wholly unreasonable.

Mr. GIBBONS (for plaintiffs) pointed out that defendant knew the nature of the goods he was buying.

DEFENDANT said that was true, but the lamps ought to have been examined in plaintiffs' factory before they were sent out, and plaintiffs must take the risk if some of the lamps arrived at his (defendant's) place damaged. He had to send them out to his customer unexamined to save handling them. He took his customer's word if they were returned broken. More lamps were broken from rough handling than from wear. He was now demanding deductions for discounts which had not been allowed.

Mr. GIBBONS said that was because defendant was not entitled to them. Defendant said there was a 20 per cent. discount on some of the lamps and 7½ per cent. trade discount on others.

Mr. GIBBONS said that the trade discount was only allowable if defendant paid in seven days, which he did not.

Judge LUMLEY SMITH found for plaintiffs for £30 and costs, plaintiffs to fetch and take back the broken lamps.

Tramway Fare Collection.

At Manchester City police court on Friday last week two tramcar passengers were charged with attempting to avoid payment of their fares. In the first case a workman (Stanhope) was said by a ticket inspector to have boarded a car going from Guide Bridge to town near Chancery-lane, and heard the guard (who was on top) ask if all passengers had tickets. Later the conductor found defendant had no ticket, and when asked where he got on he replied Chancery-lane. A woman passenger said he was on when she sat down at Bersamy-street, and eventually defendant admitted that he got on near the Halfway House, so that 1½d. was due from him.

Defendant pleaded that he had not been asked for his fare. The Clerk made the comment that he had not been asked to get on to the car, and he ought not to expect to be asked for the fare. He was fined 5s. and costs, with extra costs for two witnesses.

In the second case, that of a youth (age 15), the charge was dismissed with a caution.

T. Fairlie & Co. v. West of Scotland Billiards Co.

On Tuesday Sheriff-substitute Smith Clark issued his decision in this action brought by plaintiffs for payment of £91. 14s. 11d. for putting in new and the rearrangement of existing electrical fittings in defendants' premises. Defendants, while admitting that plaintiffs were instructed to do certain work for them, took objection to certain items which they said had not been incurred on their instructions; that no credit was allowed for goods returned, and that plaintiffs had contracted to supply certain items at prices less than those charged. Defendants tendered payment of £60. 19s. 11d. The Sheriff held that these objections to the account had no solid foundation. He found that the prices charged were reasonable and proper, and held defendants liable to pay the account, less £4. 1s. 6d. for returns, and he gave decree for the balance outstanding (£26. 13s. 6d.) with expenses.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

An assistant engineer is required by an English company operating in South America; must have had experience in station running and three-phase h.-t. working. Commencing salary £250 per annum. See an advertisement.

A telegraph and electrical instrument inspector is required for the Baro Kano Railway (Northern Nigeria) for two tours of 12 months' residential service, with possible extension. Salary £250 a year, rising to £300 by annual increments of £10. Applications to the Crown Agents for the Colonies, Whitehall-gardens, S.W., up to the 17th inst. Further particulars are given in an advertisement.

Wireless telegraph operators are required for the Canadian Navy; must be experienced men of good character. Particulars from the Captain, H.M.C.S. "Niobe," Devonport. See advertisement.

An outdoor representative is required for a London Electric Supply Co. See advertisement.

There is a vacancy for an improver (without salary) at the Watford electricity works; also for a premium pupil. Applications to the Chief Electrical Engineer. See advertisement.

Applications are invited for the vacant position of assistant lecturer in the physics department of the Technical College, Sunderland. Commencing salary £150 per annum. Particulars from the assistant clerk to the Education committee (Mr. Herbert Reed), 15, John-street, Sunderland. Applications by Sept. 10.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17.

An instructor in electrical and mechanical engineering is required at the Limerick municipal technical schools. Initial salary £130 to £150, according to qualifications. Applications to the Principal, 69, George-street, Limerick.

As announced in our last issue, Mr. A. J. Howard, chief assistant at Taunton, has been appointed borough electrical engineer, in succession to Mr. Thornhill, at a salary of £200. The four candidates selected for interview by the Electricity committee were Mr. A. J. Howard (Taunton), Mr. A. W. Clay (deputy electrical engineer, Accrington), Mr. W. J. U. Sowter (engineer and manager, Bray), and Mr. W. F. Stamp (deputy electrical engineer, Devonport). The final ballot was between Mr. Howard and Mr. Sowter, and the former succeeded by a majority of two votes.

Salford Electricity committee have promoted Mr. E. H. L. Dickson, mains superintendent, to the position of deputy borough electrical engineer, at his present salary of £270 per annum, rising by biennial increases of £25 to £325.

Mr. Lambert, manager of Messrs. Stevens (Ltd.), of Maidstone, has been appointed manager of the Maidstone tramways in succession to Mr. F. Saunders.

Capt. Gerald Thorp, R.E., has been appointed an instructor in the (Army) Schools of Electric Lighting, vice Capt. A. C. J. Stevens, R.E., whose appointment has expired.

On the recommendation of the Gas committee, Leicester Corporation have appointed Mr. Hubert Pooley, manager of the gas and electricity works at Stafford, to the position of manager of the Leicester gas and electric lighting undertakings, in succession to the late Mr. Alfred Colson, at a salary of £800 a year, rising by annual increments of £100 to £1,000.

EDUCATIONAL NOTICES.

University of London, Goldsmiths' College.—The new session commences on Monday, Sept. 26, and the enrolment of students commences on 19th inst. Complete courses of instruction are provided in mechanical, electrical and constructional engineering, telephony, fitting and machine pattern making and smithing, land surveying, &c. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education and City and Guilds of London Institute and for the National and Whitworth scholarships. There are reduced fees to course students if paid by Sept. 23. Particulars of fees, &c., from the Warden, Goldsmiths' College, New Cross, S.E.

University of Edinburgh.—The next session opens on Oct. 4, and the preliminary or entrance examination is held in September. In the engineering department of the University complete courses of instruction are provided in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in Engineering, and extending over a period of three years. Particulars of entrance examination

Digitized by Google

scholarships, fees, &c., can be obtained from the Matriculation Office of the University.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

University of Liverpool.—We have received a copy of a pamphlet which gives particulars of the courses of instruction provided in the Faculty of Engineering of this university. The session 1910-11 will commence on Oct. 4.

The courses of study in the faculty leading to the ordinary degree of Bachelor of Engineering extend over at least three years, and they are so arranged as to afford a general scientific training for those who intend to become engineers, naval architects, surveyors, &c. There is a course of not less than two years, leading to a certificate in engineering, for those who do not proceed to a University degree. A fourth year of study is arranged for honours students. Arrangements are made for students to spend the summer vacation in works or to take a voyage as junior engineers in steamships. Special facilities are granted to graduates of other universities who wish to pursue some special branch of engineering or to carry out research work.

University College of North Wales (Bangor).—In October a systematic course of instruction in electrical measurements and practical electricity for students proposing to enter the profession of electrical engineering will be commenced. The physical laboratory is well equipped for experimental and research work. The course extends over two sessions. Prospectus and further information may be obtained from the secretary and registrar, Mr. J. E. Lloyd, M.A.

Merchant Venturers' Technical College.—The faculty of Engineering of the University of Bristol is provided and maintained at the Merchant Venturers' Technical College. There are complete courses of instruction in civil, mechanical, electrical, mining and motor car engineering. Calendar (6d.) or prospectus (1d.) may be obtained from the Registrar.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

Sir John Cass Technical Institute.—At this institute there are evening classes in chemistry, metallurgy, physics and mathematics, and the courses are designed to meet the requirements of those engaged in chemical, metallurgical and electrical industries, and in trades associated therewith. Facilities are given for special and advanced practical work in well equipped laboratories both in the afternoon and evening. The instruction in general physics and mathematics will prepare for the final B.Sc. examination of London University, and there are special courses on general physics and electricity and magnetism for the honours B.Sc. on induction in gases and radioactivity and on the differential and integral calculus for science students. The new session begins on Monday, 26th inst. Particulars of the courses can be obtained at the offices of the Institute, Jewry-street, Aldgate, London, E.C., or by letter of the Principal.

Battersea Polytechnic (London, S.W.).—The day courses at this Polytechnic prepare for the B.Sc. degree (in engineering) of the University of London, and for the Polytechnic diploma in mechanical, electrical, civil and constructional engineering. The day courses commence on 22nd inst. and the evening courses in the same subjects on 26th inst. Prospectuses from the Secretary.

BRITISH NOTES.

Accrington.—In order to be able to meet the increased demand for electric current entailed by the supply to Haslingden and Church the Council have purchased some plant recently in use at the Millbank station of the Westminster Electric Supply Corpn., London. The total cost of the extensions (plant, buildings and mains) for giving a bulk supply to Haslingden will be £9,687, and new cables to Church will cost about £1,000. Sanction to a loan of £16,359 has been applied for. Oswaldtwistle Council has also asked for terms for supplying electricity for power and lighting.

Aldeburgh.—Messrs. Christy Bros. & Co. have intimated that they will apply for a provisional order.

Application for Restoration of Lapsed Patent.—The Aktiebolaget L. M. Eriesson & Co. have applied for the restoration of the patent granted to Kjöbenhavna Telefon-Aktieselskab for "Improved apparatus for the automatic distribution of the operating service in telephone exchanges," numbered 14,851/1906, which expired on June 30, 1909, owing to non-payment of renewal fee. Notices of opposition must be sent to the Patent Office, London, by Oct. 31.

Barrow-in-Furness.—The Council have decided to consider the question of exercising their option of purchasing the local tramways from the British Electric Traction Co.

Application is to be made for sanction to borrow £5,000 for mains, services, &c.

Bath.—The Board of Trade have intimated to the Rural Council that their electric lighting order will be revoked as a portion of the area has been included in the order granted to the Corporation.

Bexley Heath.—Notice of three resolutions relative to the position of the electrical engineer and tramways manager had been given for the last meeting of the Council.

Coun. FRANKLIN, who moved "That the electrical engineer and tramways manager be given three months' notice to terminate his appointment," said he believed there was not a member of the Council who did not really feel that a change in the management of the tramway system was desired. He had nothing whatever to say against the manager as a man, but he was bound to remark that somehow or other he had not done sufficient to make the concern pay. He believed that if they had a fresh man who was capable he would, after 12 months' trial, make it pay.

Mr. SMITH moved, as an amendment, "That having regard to the last report from the Electric Light and Traction committee as to the deficit on the tramway undertaking, the Council give instructions for the immediate preparation of the financial statement of the working, &c., for the year ended March 31, 1910, and to fix at an early date when the same shall be considered by the Council with a view to affording an explanation to ratepayers generally, and particularly those in parts of the district who bear their portion of the burdens of deficit but do not partake in any advantages."

Mr. BAKER BEALL, who seconded, said that they should not blame their manager. The real fact was that the whole of the loss was due to the Council itself, and to its abominable business in managing.

The amendment was carried, the other two motions being ruled out of order.

Blackburn.—The Council decided last week that all tramcar drivers must be examined by the medical officer of health at least twice a year.

Bognor.—The Chichester Electric Light & Power Co. have notified the Council of their intention to apply for a provisional order, and the clerk has been instructed to ask five consulting firms to state their fees for reporting on an electricity scheme.

Bootle.—The Council have decided to apply for sanction to a loan of £8,500 for extensions of the electric supply cables and feeders and for meters, services, &c.

Brighton.—At the meeting last week the Council adopted the report and recommendations of the Lighting committee in regard to the renewal of the condensing pipes, &c., at the Southwick power station owing to the obstruction of the old pipes by mussels and other marine growths.

Cleckheaton.—An unopposed inquiry was held on Tuesday into the Council's application for sanction to borrow £2,210 for extensions of the electric cables and services.

Coventry.—The Corporation, who will have the option of acquiring the local tramways in February next, have appointed a special committee to consider and report upon the advisability of exercising the option.

Darlington.—The Electricity & Tramways committee have reduced the rent of meters by 50 per cent.

Electric Sewage Pumping.—An L.G. Board inquiry has been held into an application of Doncaster Council for sanction to a loan for works of sewerage and sewage disposal for Owston and Skellow, where a large colliery is being constructed.

The scheme, which has been prepared by Messrs. D. Balfour & Son, consists in the laying of several miles of main sewers of c.-i. and stoneware pipes surrounded by concrete, which will be conveyed to an underground pumping station where the sewage will be automatically pumped by electric motors driving centrifugal pumps to the site of the purification works.

Electricity in Collieries.—At the recent meeting of Bolckow, Vaughan & Co., the chairman said that during the past year they had spent nearly £31,000 out of profits on extensions, plant, &c., consisting principally of expenditure at their collieries and of electrical installations, haulage, &c., rendered necessary by the Miners Eight Hours Act.

Digitized by Google

The Gwaun Cae Curwen Colliery Co. (Rotherham) recently made a fresh issue of capital, of which £70,000 will be required to sink and equip a new pit and to put down an electric power and lighting installation.

In order to give a supply of electrical energy for power and lighting to the Glebe pit of the Washington Colliery Co. a sub-station is being erected by the Country of Durham Electrical Power Distribution Co., in which there will be two 300 H.P. oil-cooled transformers.

Exhibition.—It is stated that the High Commissioners for South Africa, Canada and Australia have promised assistance for the British Imperial Exhibition which it is proposed to hold in London in 1914 or 1915.

Felling.—The Council have agreed to consider proposals for extending the tramways from Felling, through Hebburn to Jarrow.

Firing Explosives in Mines.—The Home Secretary made an order on Aug. 12 last under sec. 6 of the Coal Mines Regulation Act, 1896, repealing so much of the Explosives in Coal Mines Order of Feb. 21, 1910, as allows a charge to be fired by a permitted igniter fuze.

Greenock.—The Electricity committee recommend that the price charged for public arc lighting be reduced from £18 to £15 per lamp per annum.

Halifax.—On Wednesday the Corporation adopted a recommendation of the Tramways and Electricity committee that tenders be invited for the supply of additional generating plant at an estimated cost of £10,185.

Ald. COLLINSON moved that the minute be referred back. When the electricity charges were last fixed it was stated that the supply was greater than the demand, and that the committee wanted large customers for electricity at a very reduced price in order to get a day load. The cost of generating electricity (excluding charges for management, rates and general purposes) was 1·26d. per unit, but some large customers were being supplied at 0·83d. per unit. He contended that every unit s old for power under 1·26d. entailed an actual loss to the Corporation, and he asked that the committee should revise their charges.

Mr. A. FAWCETT said the committee would have to do something very shortly or some Saturday night they would be having a portion of the town in darkness or the trams stopped. They were buying a rotary converter for £800 in order to get through this winter. During the last two years the current supplied from the works had increased by 1,000,000 units. They could sell electricity at less than 0·83d. per unit.

Mr. C. F. SPENCER, chairman of the committee, admitted that he was not convinced the charges were on a proper basis. Before the committee came to any decision to accept tenders they would present a full report to the Council. There was a question of spending £50,000 on the electricity works. They wanted manufacturers in the town and to assist them with cheap electric power.

The amendment was lost, and the minutes were afterwards adopted.

Holmfirth.—The Council recently wrote to the Newmill and Meltham Councils suggesting that they should make a joint request to the Yorkshire Electric Power Co. to extend their mains and give a supply of electricity in the three districts.

Newmill Council have written that as many members of their Council as could make it convenient would attend the proposed meeting of representatives of the districts; but Meltham Council replied that the matter had been carefully considered by them, and they had decided not to join in the application for a supply of electricity so far as Meltham was concerned. The gas works were owned by the Council and a considerable amount of money had been spent on their extension and particularly on extension of mains for street lighting. An additional expenditure on electricity supply would, therefore, not be warranted at present.

The clerk was instructed to write to the Yorkshire Co. and get their terms for supply, &c., and the matter is to be brought up again at the next meeting.

Hove.—The local omnibus company recently requested the Council to sanction the use of the railless trolley system of traction on one or two suggested routes. The Watch committee recommend the Council not to accede to the request.

International Rubber Exhibition.—We have received a pamphlet giving some particulars of the Second International Rubber and Allied Trades Exhibition, which will be held at the Royal Agricultural Hall, London, N., between June 24 and July 11, 1911. Further particulars may be obtained from the organising manager, Mr. A. Staines Manders, 75, Chancery-lane, London, W.C.

Keighley.—The Council have revised their scale of charges for direct current supplied for power and lighting as follows:—

For a half-yearly consumption of 650 units per E.H.P. 1½d. per unit, for 800 units per E.H.P. 1d. per unit, over 800 units upon terms to be agreed between the consumer and the committee. For lighting, when the consumption exceeds 1,000 units per half-year, 3½d. per unit; exceeding 2,000 units per half-year, 3d. per unit; for supply to arc lamps, 3d. per unit; heating and cooking, 1½d. per unit. The charges for power are ¼d. less per unit, and for lighting 1d. per unit less. The charges for arc lamps and for heating and cooking are new.

The charge for electricity on the three-phase e.h.t. system will be based upon a £3 per kw. maximum demand, plus ¼d. per unit. The consumer must provide a transformer on his premises, except upon special terms to be agreed with the committee; the Corporation will run the cable into the building and deliver h.t. current at the meter on consumer's premises.

Life of Tantalum Lamps.—A correspondent in Doncaster has sent to a contractor the following striking testimony to the economy and long life of tantalum lamps:—

Three years ago you put in my electric light installation in Avenue-road with Tantalum lamps. There are 10 lights in constant use. Up to now we have only required two new lamps, and the lights are as good as ever.

Malvern.—The Council have received from the Light Railway Commissioners the draft of the light railway order for the construction of the proposed funicular railway on the hills.

The company are to purchase electrical energy from the Council if it can be supplied at a reasonable price, and the Council wish to reduce the period allowed for the construction of the line from four to two years.

On the past year's working of the electricity undertaking there was a net profit of £3. 1s. 4d., compared with a loss of £653 in the previous year.

Manchester.—At the meeting of the Corporation on Wednesday a discussion took place as to the terms and conditions upon which gas would be supplied for cooking by the gas department where electricity was supplied from the Corporation's electricity department for lighting.

The Gas committee desire that, in addition to the cooker, one light shall be placed in the kitchens of houses supplied, and at a previous meeting of the Council they had been requested to reconsider the matter.

Ald. GIBSON (chairman of the Gas committee) now said that the committee adhered to their former conclusion.

Ald. WALKER asked that the matter should be again sent back and referred to the standing joint committee for consideration.

Ald. GIBSON, after a conversation with the chairman of the Electricity committee (Mr. Howarth), agreed to take the question back again, so that he could consult that chairman.

Ald. HOLT said that the question was a serious one. There was contention between two committees as to who were going to supply light. The sooner the two committees were joined together in one Light and Power committee the better it would be for the city. At present they were both contending for business, and they had no right to allow competition between the two departments.

Municipal Wiring.—In addition to the list of towns favourable to the promotion of a bill by the Incorporated Municipal Electrical Association for the amendment of the Electric Lighting Act, 1909, to enable municipal electricity undertakers to wire premises, let motors and fittings on hire, &c., we are informed that Wolverhampton and Greenock Corporations have decided to give financial support and Bray Council to give moral support to the bill.

National Electrical Manufacturers' Association.—The next committee meeting will be held at Balfour House, Finsbury-pavement, on 13th inst., at 2:30 p.m.

Oldham.—Sanction to a loan of £12,544, to meet cost (already incurred) of extending the tramway feeder cables, has been applied for by the Council.

Porlock.—Last week a public meeting (presided over by Sir F. Carruthers Gould) was held to consider an electric lighting scheme for Porlock and Doverhay. Mr. C. H. Steele (Messrs. J. & W. Purves) attended and supplied technical details. The meeting appeared to be in favour of the scheme.

Portrush.—The Council are to have an interview with Mr. H. V. Pegg (of Messrs. Miller, Wilson & Pegg) as to an electricity scheme for the district.

Presentations.—Burslem electricity staff has presented a travelling case to Mr. A. Bremner, the late electrical engineer and manager.

Castleford tramway staff and employés have presented a timepiece to chief inspector W. Wilde, who has been appointed traffic superintendent of the Wakefield & District Light Railways Co.

On Friday last Mr. J. W. Fraser was the recipient of a writing case subscribed for by the employés of the L.C.C. tramways power house (Greenwich) on his leaving the department to take up a Government appointment.

Railway Returns.—The returns of the capital, traffic receipts, &c., of the railway companies of the United Kingdom for 1909 have been issued as a Blue Book.

The total paid-up capital of the companies was £1,314,000,000, an increase of £3,250,000 compared with 1908, £16,500,000 in 1908 and £7,750 000 in 1907. The average rate of dividend on the ordinary capital was 3·15 per cent., against 2·99 per cent., and on the preference capital 3·46 against 3·42 per cent. There was a decrease of about £500,000 in passenger traffics and a decrease of 8,269,000 in the third-class passengers carried.

The number of passengers conveyed by the "tube" railways of the

Digitized by Google

Metropolis exceeded 168,000,000 in 1909, compared with 161,000,000 in 1908. In spite of this increase, the gross receipts of the "tube" railways from ordinary passengers decreased by £6,000, or 0·5 per cent.

The total working expenditure of the whole of the companies fell from £76,408,000 in 1908 to £75,038,000 in 1909, and the proportion of working expenses to gross receipts fell from 63·7 to 62·4 per cent. In 1900 the rates and taxes amounted to £3,757,000, and in 1909 to £5,010,000, which was an increase of £126,000 on the figures for 1908. The total length of the running track of the railways of the United Kingdom was 39,622 miles, and of sidings 14,350 miles. At the end of 1908 the length of running track was 39,316 miles, sidings 14,353 miles.

At the end of 1909 the length of line (in equivalent of single track) worked solely by electricity was 204½ miles, and 229¾ miles were being worked partly by electricity. The corresponding lengths of line at the end of 1908 were 204½ and 200¼ miles respectively. The total quantity of electrical energy used in 1909 was 253,294,628 units, compared with 249,287,308 in 1908.

Rochdale.—On the recommendation of the electrical engineer (Mr. C. C. Aitchison), the Gas and Electricity committee recommend the Council to adopt a revised scale of charging for the supply of energy for power. The scale will only apply to consumers having over 15 H.P. installed, and will come into force on Oct. 1.

Over 250 and not exceeding 300 units per quarter per b.h.p. installed, 1d. per unit, between 300 and 350 units 0·9d., 350 and 400 0·8d., 400 and 450 0·7d., over 450 units 0·6d. An alternative system will be available of 25s. per quarter per e.h.p. of maximum demand and a flat rate of ¼d. per unit, which will apply to consumers having a total of over 20 H.P. installed.

In future no motors are to be let out on hire without an agreement by the consumers hiring them to pay the ordinary rental for a period of not less than three years in addition to the existing regulations.

Stalybridge.—An inquiry was held last week into the application of the Stalybridge, Hyde, Mossley and Dukinfield Joint Tramways and Electricity Board for sanction to a loan of £22,268 for extensions of the electricity undertaking.

Stevenage.—The L.G. Board have requested the Council to inform them within two months what steps have been taken to carry out their obligations under their provisional electric lighting order, 1902.

The late H. W. Cox.—The total amount received up to Sept. 1 by Ald. Sir W. Treloar on behalf of the widow and children of the late Mr. Harry W. Cox was £3,405. 10s. 9d. It is intended to close the fund at the end of September. The money has been invested in the names of Sir W. P. Treloar, Sir W. H. Dunn, M.P., and Dr. Alexander. Donations can be forwarded to 69, Ludgate-hill, London, E.C.

Torquay.—The L.G. Board have intimated to the Council that they will sanction a loan of £4,500 to defray the cost of mains laid during the three years ending Dec. 31, 1912, provided the Council pass a supplemental resolution authorising the increase of the loan.

It was decided at the enquiry to charge to revenue account the excess expenditure of £486 incurred up to Dec. 31 last in connection with the undertaking, and that all expenditure after that date in respect of sub-stations, transformers, services and meters would also be defrayed out of that account. The practice of the Council to pool into one common fund all the loans raised for the undertaking was stated to be irregular. In future the expenditure under each sanction granted by the Board should be kept strictly separate, and the moneys borrowed under each sanction should be applied only to the specific purpose for which the loan was authorised.

On Tuesday the Council decided to ask the L.G. Board to increase the amount of the loan to £4,500.

In connection with the arbitration proceedings as to the system of traction to be adopted in place of the Dolter surface-contact system, the Council have decided to be legally represented and to call Mr. Mordey and other witnesses in support of their case.

Warrington.—The L.G. Board have sanctioned the borrowing of £6,257 for additional generating plant at the electricity works.

West Ham.—In reference to the recent loans for electricity supply extensions sanctioned by the L.G. Board, we are informed that the amount of the last application to the Board was £55,000, but at the local inquiry £2,000 in respect of certain sub-station equipment was withdrawn by the Corporation as the inspector (Mr. H. R. Hooper) stated that it would be in order if that expenditure was defrayed from a previous application for transformers which was not expended. The amount applied for has, therefore, been sanctioned in full.

The inquiry into the last application took place on July 27, and the loan was sanctioned on Aug. 16—surely a record.

Wigan.—The water department is considering a report of the borough electrical engineer (Mr. J. Slevin) recommending the installing of two electrically-driven centrifugal pumps at the pumping station.

Application is to be made to the Board of Trade to sanction the borrowing of £2,700 for extensions of present tramway loops and

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,086 pages), bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

construction of additional loops, and £4,200 for six new single truck double-deck cars.

A discussion took place at Wednesday's meeting of the Council on the recent report of Mr. C. W. Mallins on the present position of the tramways.

The chairman of the Tramways committee (Ald. ASHTON) drew attention to resolutions which had been passed, on the recommendation of Mr. Mallins, for extensions of present loops and the provision of additional loops; and he moved that those resolutions should be referred back, in order that they might have a report from their own traffic manager. Before going to further expense they should pay attention to Mr. Mallins's recommendations as to improving the local service with the aid of the existing rolling stock.

Mr. M'QUAID said they were trifling with the tramways, which were going from bad to worse.

Mr. BRADSHAW urged the appointment of a general manager of the whole undertaking.

The resolution was carried, on the understanding that the committee formulated its recommendations on the whole of Mr. Mallin's report, and submit those recommendations to a special Council meeting.

Wireless Telegraph Notes.—In some important experiments in aeronautics which are being carried out by the British War Office the wireless control of airships and the establishment of communication between these vessels and terra firma are being attempted.

It is announced that arrangements have been made by the Government of Panama with an important commercial undertaking (the United Fruit Co.) for the establishment of a wireless telegraph station at Colon, where commercial messages will be received for Botas del Toro and Port Linion (Costa Rica), two districts where the fruit company carry on extensive operations. It is further reported that the Director of Posts and Telegraphs (Mr. E. Lefevre) has under consideration a project for establishing wireless stations to link up Panama with the coasts of Ecuador, Peru and Chili.

Important experiments are being carried out at Torbay in the use of wireless telegraphy in connection with submarine vessels. It is stated that the vessels have received messages successfully, but that no message from the submarines has been successfully received from the land station at Babbicombe Bay.

It is announced that the British Government authorities have made arrangements to establish at Gibraltar, Malta, Aden and Perim Island powerful installations of wireless telegraphy, and that there is a possibility that Cyprus, Alexandria and other places may be similarly connected up by wireless.

Another life-saving feat has been placed to the credit of wireless telegraphy. A British steamer, the "West Point," took fire in mid-Atlantic, and, but for wireless telegraphy, the safety of the entire crew would have been seriously endangered. Two vessels (the "Dovonian" and the "Mauretania") were successful in picking up two boatloads of the crew of the "West Point." The "Devonian" first picked up one of the boats, and, by means of wireless, put the "Mauretania" in possession of the facts and enabled her to pick up the second boat.

Some changes have been made in the arrangements for the establishment of wireless telegraph stations in the Pacific. It will be remembered that tenders were invited recently for the erection and equipment of stations at Sydney and Fremantle. It was arranged that the former station should be erected in the vicinity of what is known as Sydney Heads. The Commonwealth authorities have since decided that a more advantageous position would be at Pennant Hills, further inland, and about 13 miles from Sydney, on the railway towards Newcastle. The change has involved an additional expenditure of £2,000 on the station, the contractors (the Australian Wireless, Ltd.) stating that the station will be more expensive to erect, because of the land intervening between the sea requiring more power than would be the case at the Heads, and because greater expense has to be incurred in earthing and protecting the terminal wires. Near the coast, it is urged, better earthing can be effected than inland, and a coastal station can radiate a greater amount of energy than one inland with the same power. These reasons for the extra expenditure are admitted to be sound, but the Federal Government considers that the company has amply secured itself against loss by the change.

Wireless Telephony Notes.—Mr. W. Woodcock, of Clitheroe, Lancs., is reported to have been successful in conducting a number of experiments in wireless telephony.

Digitized by Google

It is reported that Mr. John Burns, of Portobello, Edinburgh, has been successful in devising a means of transmitting the voice a distance of over 1 mile, and that some patents which he has taken out are being acquired by a local syndicate with a view to erecting a station at Burntisland, 10 miles from Portobello, to enable the continuance of the experiments which have been going on for some time at Portobello.

Workhouse Lighting.—Poplar (London) Guardians have received a communication from the L.G. Board as to their proposal to engage Messrs. Jackson, Pixley & Co. to make certain inquiries with a view to ascertaining the relative cost of electric current generated on the workhouse premises or obtained from the mains of Poplar Borough Council.

The L.G. Board suggest that the Guardians should first instruct their engineer to prepare a report showing the average cost of generating current during the last three years, and the capital charges, and showing what saving would be effected by obtaining a supply from the mains of the Council, and that a copy of the report should be forwarded to the Board, with the observations of the Guardians thereon. The letter has been referred to the Workhouse committee.

Electrical Engineers (London Division).—The Bohemian concert of this corps, which was postponed on account of the death of King Edward, will be held in the Pillar Hall, Victoria Station (S.E. & C.R.) on Saturday, Oct. 15., at 7:30. Tickets and all information may be obtained from the secretary, C.S.-M. A. E. Dixon, at the Headquarters of the Corps, Regency-street, S.W.

COLONIAL AND FOREIGN NOTES.

As the Cordoba Electric Light Co. have built a new steam-driven station in the city, the steam-power station built by the Government some time ago is no longer required, and will shortly be put up for sale.

Australasia.—The "Australian Mining Standard" says Newcastle (N.S.W.) Council has appointed a committee to inquire into the working of the electricity department, and an expert is to be engaged to advise at a fee of 25 guineas.

At a recent public meeting at *Toora* (Victoria) it was decided to form a company to provide electricity supply. Mr. Jas. Allan, who presided, said he and Mr. A. H. Wood (electrical engineer, of Melbourne) were prepared to take up half the initial capital (£500). The initial plant would be about 75 H.P. and water power would be used in generating current.

A deputation appointed by *Yarrawonga* (Victoria) Shire Council to inspect various provincial electricity works have reported in favour of electricity supply, and the Council have therefore decided to establish an electricity generating station.

The electrical generating plant at *Korumburra* (Victoria) was recently started. The plant comprises a Gardner four-cylinder vertical engine (supplied with gas by a Grice's suction gas plant) and a 56 kw. Mawdsley generator. By using a 500 ampere-hour battery it is expected that a sufficient supply of energy can be maintained day and night. Capital expenditure is £2,500.

Melbourne Council have arranged to take into their electricity supply department each year two students from the Working Men's College, at salaries of £1 per week. The appointments are for one year, the object of the experiment being to provide suitable candidates from whom the committee can select men for subsequent vacancies in the service.

Charlton (Victoria) Shire Council have accepted the offer of the local electric lighting company to provide 32 lamps of a total candle-power of 1,440 and supply current to same and also to provide and maintain two kerosene lamps in outlying parts for £100 a year.

Australian Wiring Rules.—The Fire Underwriters' Association of Victoria, who have adopted (with a few modifications to meet local circumstances) the wiring rules of the Institution of Electrical Engineers, have now added the following to rule 62:—

Where switch and distribution boards are placed on or within 6 in. of a wooden wall or 18 in. of a wooden ceiling, a thickness of some hard insulating fire-resisting material, such as a composition of asbestos or other mineral ingredient, is to be placed between such switch and distribution board and such wall or ceiling, and extending at least 6 in. beyond the board all around. Wires, &c., going through this material should fit as tightly as possible the holes through which they pass.

Austria-Hungary.—Smichow communal authorities are about to construct an electric tramway to Neu-Smichow and Malvazmka-Friedhof at a cost of about 1 million kronen (£42,000).

Chili.—A report by Consul-General A. Finn states that imports into Chili in 1908 included electrical machinery 7,448 tons (compared with 3,432 in 1907 and 2,014 in 1906), including 1,059 (against 1,422 and 546) from the United Kingdom, 5,582 (1,512 and 951) from Germany, 406 (454 and 494) from the U.S.A. and 401 (44 and 22) from other countries; scientific instruments, total 61 tons (against 63 in 1907), United Kingdom 14 tons (against 18), Germany 35 (26), France 7 (4), and U.S.A. (14).

Vice-Consul Steel says the electric tramways, which are a new feature in the town of Talcahuano, have done much to distribute the growing population.

Customs Duties.—According to recent decisions the following duties are leviable under the Australian import tariff:—

Printed paper cartons enclosing zinc boxes used in the manufacture of dry cells (British or foreign) 6d. per lb., or 35 per cent. ad val., whichever is higher; zinc boxes, general tariff 17½ (British goods 10) per cent.; portable electric cranes (motor, controller, crane and truck) 25 (British 20) per cent.; motor tramcars 30 (British 20) per cent.

The following (British or foreign) are duty free: Fuse boxes (one fuse in a box) and educational apparatus for teaching engineering, mechanics, metallurgy, mineralogy, physics, &c., in schools, colleges or universities.

Dawson City (British Columbia).—It is announced that the power house of the Northern Light, Power & Coal Co. was completed on Aug. 24, and electric current was transmitted over 44 miles to Dawson City, where there are already a number of power and lighting consumers of the company.

South Africa.—The "British and South African Export Gazette" reports that an extension of the *Pretoria* electricity works is in hand.

The Council are endeavouring to promote the use of electricity for cooking, heating, &c., and an opportunity now offers to British makers of electric cookers and heaters.

The Pretoria municipal tramcars will be running by October. The cars are single deckers, supplied by Dick, Kerr & Co., but the rails are of American manufacture.

The concession for the erection of an electricity generating station at *Tweefontein* has been obtained by Mr. Howard Pim, on behalf of the Transvaal Hydraulic Power Synd., and a company is to be formed with a capital of £926,000. It is understood that electro-chemical works will be started in connection with the power station.

Benoni Municipality have placed an order in England for electrical material.

The *Transvaal* Gold Mining Estates (Ltd.) are about to purchase a large power plant, and electrical plant was recently imported for *Utrecht* colliery.

The introduction of Osram lamps has (it is stated) saved *Bulawayo* Corporation over £2,000 per annum in public lighting.

The proposal of *Potchefstroom* Municipality to adopt an electricity scheme (to cost £20,000) is to form the subject of a Government inquiry.

It is proposed to spend £150,000 on the improvement of *Capetown* docks, including a sum for an electric travelling crane.

An order for a battery and Entz booster for the *Delagoa Bay* Port and Railway Council has been placed with the Chloride Electrical Storage Co.

Dick, Kerr & Co. have secured orders for spares for tramcars and water vans for *Johannesburg* Council.

Spain.—The Cia del Tranvia de Bilbao recently obtained a concession for the construction and working of an electric tramway in Bilbao.

Uruguay.—The "Review of the River Plate" says the report of the Government electric power undertaking at Montevideo for 1907-8 and 1908-9 has been published.

For 1907-8 the profit was $142,536.47, for 1903-9 $166,915.71, and for the first eight months of 1909-10, $122,921.24, representing a profit of 18 per cent., 19 per cent. and 9 per cent. respectively on the capital. The profits have been reduced by loss on the municipal service and by reductions in tariff, which within two years was reduced from $0.15 to $0.10 for Government supplies, and on July 1, 1909, the average price paid by private individuals was reduced from $0.21 to $0.12. As regards lighting on Feb. 28 last the number of lamps for private use were: Incandescents 126,734, arcs 324, other 711, the number of customers being 8,166; for public lighting there were 4,324 incandescents and 753 arcs. On June 30, 1909, there were 151 electric motors in use, total 821 H.P., and on Feb. 28 of this year the number had increased to 471 motors and 2,110 H.P.

The electric tramways in Montevideo during the half-year ended June last carried 30,183,060 passengers, compared with 26,622,750 in the first half of 1909. The car-miles run were 6,730,854, against 6,221,078.

Uruguay.—Señor A. Rossi has obtained a concession to construct telephone lines from Villa del Carmelo to Colonia Arrué, to Ombúes de Lavalle and to Paseo de Camacho (44 miles in all).

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Aberdeen.—The accounts of the electricity department for the year ended July 31 have been issued.

The total revenue was £45,219, decrease £572 compared with 1909. Revenue from sale of current by meter was £31,765, public lighting £2,326, traction (less £1,267 difference between amount charged and actual cost) £8,716, and current supplied to the Suburban Tramways Co. £1,070, hire of motors £1,633. Expenditure amounted to £19,849, increase £227, leaving a balance of £25,370. The principal items of expenditure were: Fuel £7,053, oil, waste, &c., £314, wages £2,003, repairs of buildings £394, repairs of plant £898, total £10,663 for cost of generation; distribution cost £711; rents, feu-duties and taxes £5,225, management £1,665, motor repairs £412, depreciation of motors £487, bad debts, &c., £380, and special services £302. Interest absorbed £9,426, sinking fund £14,553, one-fifth of cost of Aberdeen Corporation Electricity Act (third instalment) £477, and surplus carried to reserve £967. The amount of reserve is now £13,832. Total capital expended is £368,618, amount borrowed on mortgage £226,999, and mortgages redeemed by sinking fund £58,841. During the year 6,416,276 units of energy were generated, compared with 6,070,192 units last year. The total quantity sold was

Digitized by Google

5,436,065 units (against 5,170,121), including 3,141,749 to consumers by meter, 291,435 for public lighting, 1,856,089 for Corporation traction and 146,792 for suburban traction. The total number of public arc lamps was 204, same as last year.

In the report of the city electrical engineer (Mr. J. Alex. Bell) it is stated that some of the features of the year were the satisfactory start and the boom given to electric heating by the hiring out of apparatus and the amended price for supply of this nature; all supply for outlying districts had been given from Ferryhill generating station, the reduction in price per unit charged for Corporation tramway supply, and the continued drop in the cost of production. The flat rate for lighting and the graduated scale for power had so far proved satisfactory. It was probable that their reduced output for lighting during the first six months of the year was to a small extent due to the caution exercised by consumers until their first half-year's accounts under the new charges were obtained. The additions made to heating apparatus was in itself a justification of the policy of hiring out, commenced August, 1909. The total heating apparatus coupled at the end of 1908-9 equalled 5,633 33-watt lamps; by the end of 1909-10 the figure had risen to 11,358 33-watt lamps. In one year, therefore, they had doubled the total heating connections. It was interesting to note that, of these additions, the apparatus sold by contractors equalled their best year—thus showing that entirely new ground had been broken by the department in the hiring out system, with advantage, not only to the electricity department, but to the electrical contractors, who obtained all the wiring for the work. The effect of the installation of the metal filament lamp was still apparent on the output; but there were compensations, as they could now obtain a class of consumer impossible in the days of carbon filament lamps. In the Deeside districts, for instance, the smallest cottages were now regularly wired for electric light. The Aberdeen architects were, to a large extent, still installing gas for lighting in small houses within the city, and he was inclined to think they neglected the fact that a thoroughly sound and satisfactory installation of electricity was as cheap to install—and, nowadays, practically as cheap light for light—as gas, irrespective of the many incidental advantages which electricity could claim. 181 new consumers were added during the year. Motors (representing 387 H.P.) had been coupled up since last report. The alterations of copper strip culverts were nearing completion. At Cults sub-station a three-phase motor was fitted to one of the dynamos originally steam-driven. The output for private lighting consumers was 99,225 and for power and heating consumers 258,040 units in excess of previous year. That satisfactory increase in power would continue as trade got better. Heating units had increased from 18,541 to 41,614. The smaller heating and cooking apparatus was in many cases used direct off lighting circuits. The Deeside district again showed a most satisfactory increase, the units having increased 30 per cent. during the year. Supply had been available for a complete year to the Woodside and Bucksburn districts, and the output sold amounted to 45,047 units. The Corporation tramways consumption showed a decrease of 90,442 units. The works costs for the year and total costs had reached the lowest level yet attained. The increased price of coal was responsible for a slight rise in works costs, but that had been more than made up by reductions in other directions. The new scale of charges has given satisfaction, and with one exception (heating) should remain the same for another 12 months. Mr. Bell recommends that the charge for electricity for heating be reduced from 1½d. to 1d. per unit. He has no doubt that the reduced charge will result in a largely increased output in that direction.

On the recommendation of Mr. Bell the Electricity committee have decided to grant a bonus of £25 for six months to employés in the engine room and boiler house as an additional inducement to practice economy.

The committee have decided to extend the mains to the Aberdeen and North of Scotland College of Agriculture provided the college authorities guarantee a minimum consumption equivalent to £50 per annum for five years from the date of commencement of supply, and the cost of all service cables required beyond the lodge gates of Craibstone House must be borne by the college.

Barnsley.—The capital borrowed for the electricity department is £75,499 and amount repaid £5,351. Capital expenditure is £77,441, increase £1,271 during the year ended March last.

The income during the year was £12,705, total expenditure £5,687, and gross profit £7,018. Interest, sinking fund and instalments of loans required £5,219, leaving £1,800 net profit. Units generated were 1,794,588, and 281,592 were supplied to public lamps, 296,876 sold by contract and 913,477 by meter. The total maximum demand was 822 kw.

Bradford.—The statement of accounts of the tramways department for the year ended March 31 shows total income £259,696, including £245,682 traffic revenue and £8,169 for carriage of parcels.

Working expenses of the tramways department were £161,951 and of the parcels department £6,330. The cost of the motor garage and Bowling-hill departments increased the expenses to £170,689, leaving gross profit £88,997. Interest on capital absorbed £22,407, income tax £2,250 and rent of leased lines £4,137. The repayment of mortgage loans and contribution to sinking fund came to £30,454; £20,000 was devoted to relief of city rate, and the balance (£12,365) was placed to reserve or renewals fund. The gross capital expenditure is £930,114 (an increase of £6,599), but nearly £300,000 has been repaid. Passengers carried were 50,518,813 (increase 2,858,802 over 1909) and the car-miles run 5,436,529 (increase 60,301). The average fare paid per passenger was 1·167d. (against 1·165d.). There was an increase of £503 in the total expenses; but power expenses were 2·073d. per car-mile (against 2·115d.), and repairs and maintenance 1·432d. (against 1·393d.). There was a net profit of £1,741 on the parcels department, against £1,028 in 1908-9.

Govan.—The annual report of the burgh electrical engineer (Mr. Theo. C. Parsons) together with the accounts of the electricity department for the year ended May 15 have been issued.

The total income (£18,590) included £14,636 from sale of current by meter and £3,305 from public lighting. Total expenditure was £9,656 and gross profit £8,935. Interest absorbed £3,830, sinking fund £3,246, and after providing for depreciation on motors let on hire (£186), arc lamps let on hire (£27. 10s.), and paying £12. 5s. loss on motor sold, £1,601 was placed to renewals reserve. 3,159,311 units were generated (against 2,877,979 in 1908-9) and 2,624,684 units were sold (2,164,136 to private consumers and 460,548 for public lighting), against 2,356,367. There are 215 10-ampere arc lamps for street lighting, the maximum supply demanded was 1,736 kw., and the load factor was 17·2 per cent. (against 18·1 per cent.) The total working costs were 0·813d. per unit and the total costs (including interest and sinking fund) 1·461d.

In Mr. Parsons' report it is stated that capital expended during the year on motor hiring, &c., was £240, bringing the net total outstanding to £3,886. The total of the motor depreciation fund is £862 or 22·2 per cent. There are 68 motors (745 H.P.) on hire, and there were 62 arc lamps on hire at May 15, a decrease of 17. Metal filament lamps are superseding small arc lamps, and no fresh capital was expended during the year on arc lamps, which stands at £279. The arc lamp rents (£46) average 16·3 per cent. on the capital. In the past year, after paying all charges, including repairs, maintenance, depreciation, interest and sinking fund, there was a credit balance of £59 on the motor department and a debit balance of £20 on the arc lamp department. All stair lighting has been changed from 8 and 5 c.p. carbon filament to 30 c.p. metal filament lamps, the price charged being the same as formerly for a 5 c.p. lamp. The increase in the units sold for lighting was 6·9 per cent. and for power 17·2 per cent. There were 67 additional customers, an increase of 6·8 per cent. The total capital expenditure to date is £132,466, but deducting the motor and arc lamp capital, the total is £127,467.

Melbourne (Australia).—For the year ended Feb. 28 the City Council's electricity undertaking showed gross revenue £113,578 (increase £10,943) and working expenses £54,662, leaving gross profit £58,916.

Interest required £42,187, and after providing for depreciation, renewals, &c., the balance was £16,728. Capital expenditure during the year was £19,043. The increase in consumers was 359, compared with 351 in previous year. The Electric Supply committee have brought forward a reduced scale of flat rates for lighting, varying from 3d. to 4½d. per unit, according to the quantity consumed. Motors connected increased from 1,218 to 1,441 (4,684 H.P.).

Shoreditch (London).—The accounts of the electricity undertaking for the year ended March 31 show an increase of income (compared with 1909) of £1,598, while expenditure showed a reduction of £1,031. 19s. 3d.

The gross profit was £23,876 against £21,335, and after paying capital charges the surplus is £6,431 which is disposed of by wiping off the debit balance brought forward, and by transferring £1,486 to change of pressure account, and placing £4,000 to reserve, leaving £616 to be carried forward. The total costs per unit sold show a reduction of 0·28d. The present form of consumers' agreements, enabling the Council to require consumers to take a two years' supply, is to be amended by the substitution of the following words for the existing clause:

"The consumer shall continue to receive and pay for a supply of electric energy for a period of at least two years, and the minimum payment per annum shall not be less than 20 per cent. on the outlay incurred by the Council in providing any electric lines and apparatus required for the purpose of such supply, unless a responsible tenant of such premises succeeds the applicant in agreeing in writing to take a supply of electric energy on similar terms from the Council."

Southend-on-Sea.—The total net income of the electricity department for the year ended March 31 was £26,104.

The gross revenue from the sales of electricity to private consumers for light and power was £17,663, and from the Corporation departments for light, power and traction £7,956. The total working expenses were £10,077, leaving a gross profit of £16,027. Interest (including income tax) absorbed £4,422 and instalments of loan repaid £10,132, and after providing for other small items (including £285 balance of cost of superseded plant written off) there was a net balance of £3,022 carried forward, against £2,036 in 1909. The total net capital expended is £129,645, an increase of £4,859.

The total receipts of the light railways department for the past year were £26,739, including £26,340 traffic revenue. The working expenses came to £18,734, leaving a gross profit of £8,004. Interest on loans absorbed £3,066 and instalments of loans £1,384, and £107 was transferred in respect of superseded work; £1,000 was applied in relief of rates and the net profit (£2,947. 12s. 3½d.) was carried forward. 5,802,132 passengers were carried and 527,393 car-miles run, the average receipts per car-mile being 12·16d. The total capital expended is £107,964, an increase of £2,826.

Wellington (N.Z.).—The accounts of the tramways and electric lighting departments of the Corporation for the year ended March 31 have been issued.

The total income of the tramways department was £139,460, including £130,711 traffic receipts and £8,416 from the sale of electrical energy. Working expenses were £92,947 and gross profit was £46,514. Interest on loans (for tramways, power supply and public lighting) absorbed £21,134, sinking fund £5,054 and depreciation £14,202, leaving net profit

Digitized by Google

£6,124. The total capital expenditure is £595,782, an increase of £19,408 during the year. 21,932,507 passengers were carried, and 2,203,666 car-miles run. 4,371,921 units of current were consumed for traction and car lighting, or 1·98 per car-mile.

The income of the electricity department was £44,814. Working expenses were £25,934 and gross profit was £18,880. Interest on capital came to £7,161, sinking fund to £3,130 and depreciation to £6,361, leaving a net surplus of £2,228. Capital expenditure is £217,961, an increase of £21,470. Units sold amounted to 2,018,526 (1,320,183 for private and 336,067 for street lighting and 362,276 for power and heating), against 2,004,304 in 1908-9, the increase being due to an advance of over 200,000 units used for street lighting. The equivalent of 170,627 8 c.p. lamps (against 159,865 8 c.p.) is connected, including 1,187 H.P. (1,169 H.P.) of motors. There are 4,501 consumers (4,136), including 4,147 for lighting (3,821), 241 for power (244) and 113 for heating (71). The average working expenses per unit sold were 3·08d. (2·99d.), and the total expenses 5·06d. (4·79d.).

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Electricity and Tramways committee of the County Borough of NEWPORT (Mon.) invite tenders for material required for the extension of the works in hand, including rubber cables of various sizes, single-phase l.t. and h.t. paper lead-covered cable and e.h.t. cable, welded steel, or solid drawn steam pipes, valves and cast-steel tees, rolled steel girders, c.i. and w.i. switch gallery railing, two c.i. stanchions, motor starters and other switchboard apparatus (l.t.) and c.i. flanged water pipes. Particulars from the borough electrical and tramways engineer (Mr. H. Collings Bishop). Tenders must be delivered to the Town Clerk, Town Hall, Newport, Mon., by first post Tuesday Sept. 20. See an advertisement.

Tenders are invited for supply of telegraph and telephone cable (schedule No. 284) and insulators (schedules Nos. 373 and 374) to the Postmaster-General's Department, VICTORIA. Tender forms at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to noon Oct. 17 for the supply of telegraph and telephone instruments and material (as per schedules 1 to 9) to the Postmaster-General's Department in TASMANIA. Tender forms and specifications at the office of the High Commissioner, 72, Victoria-street, London, S.W. See advertisement.

LITTLEBOROUGH District Council invite tenders for the supply and delivery of alternating-current (single and three-phase) electricity meters. Specifications and forms of tender from the clerk to the Council (Mr. Geo. H. Wild), Council offices, Littleborough, to whom tenders by Tuesday, Sept. 13.

By command of the POSTMASTER-GENERAL tenders will be received until noon, Monday, Sept. 26 for supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles to be delivered at certain ports in the United Kingdom. Forms of tender from the Controller of Stores (Mr. G. Morgan), Stores Dept., G.P.O., 17-19, Bedford-street, London, W.C.

The POSTMASTER-GENERAL also requires tenders (by noon Sept. 26) for creosoting, &c., telegraph poles. Forms of tender, &c., from the Controller of Stores, 17-19, Bedford-street, London, W.C.

The directors of the Powell Duffryn Steam Coal Co. (ABERDARE) invite tenders for stores, including electrical goods. Tenders to London office (101, Leadenhall-street, E.C.) by Sept. 12.

HACKNEY (London) Council want tenders by 7 p.m. Sept. 15 for extension of main switchboard. Specification from Town Clerk, Town Hall, Mare-street, N.E.

MANCHESTER Waterworks committee invite tenders for an electric derrick crane. Tenders to Town Hall, Manchester, by 12th inst.

Tenders are invited by WALTHAMSTOW Council for supply and erection of a storage battery. Tenders to Clerk by noon Sept. 9.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. Oct. 18 for supply of 23 miles of telephone cable (specification 284) and 500 composition insulators (specification 374) and until 3 p.m. Oct. 25 for 10,000 Cordeau insulators (schedule 373). Specifications, &c., from 72, Victoria-street, London, S.W. Local representation is necessary.

Tenders are invited up to Oct. 5 for the supply of 5,000 porcelain insulators to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms at the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders will be received (up to 3 p.m. Sept. 13) by the Deputy Postmaster-General, MELBOURNE, for supply of 8,510 telephones. Local representation necessary.

The Deputy Postmaster-General, SYDNEY (N.S.W.), invites tenders (until 2:30 p.m., Oct. 5) for supply of 5,000 porcelain insulators. Local representation necessary. Specifications, &c., from 72, Victoria-street, London, S.W.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

The Calcutta Electric Supply Corpn. is prepared to receive tenders for supply, delivery and erection at their Cossipore station and sub-stations, CALCUTTA, of motor-generators, turbo-alternators and condensing plant. Copies of specifications, drawings and general conditions from the secretary (Mr. Francis R. Reeves), Salisbury House, London Wall, E.C., to whom tenders by 10 a.m. of Sept. 19.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

Digitized by Google

Tenders will be received by Tacuarembó (Uruguay) Municipality until 2 p.m. Sept. 30 for the equipment of electricity works and the supply of electric light at San Fructuoso.

Nijmegen (Holland) communal authorities want tenders by Sept. 16 for supply of tramcars. Particulars from the Gemeentebestuur, Nijmegen.

Tenders are wanted by noon Oct. 31 for supply and erection of machinery, &c., for electricity supply and water supply systems for the town of Beni-Souef (Egypt). Particulars may be obtained from Mr. A. L. Webb, C.M.G., Queen Anne's-chambers, London, S.W. Local representation is necessary.

TENDERS RECEIVED AND ACCEPTED.

Shoreditch Lighting committee obtained quotations from five firms for supplying a storage battery of 66 cells with a capacity of 750 amperes for two hours and a battery switchboard panel (with instruments, switches, &c.), and they have provisionally accepted the lowest tender, that of the Electrical Power Storage Co., at £660 and £25 for cable and connections.

Dewsbury Council have accepted the tender of Cowans (Ltd.) for switchboard controlling panel and that of the Liverpool Electric Cable Co. for cable for coupling up the turbo-generator set to the switchboard.

Keighley Council have accepted the tender of Babcock & Wilcox for supply and erection of a water-tube boiler with superheaters, stokers and pipe work at £1,458.

Zacariás Marioni y Hermano have secured the contract for an electric installation for the Buenos Ayres Custom House at 249,462 pesos (about £22,000).

Salford Council have accepted the tender of Walter Scott (Ltd.) for the supply and delivery of 500 tons of steel tramway rails at £6. 16s. 6d. per ton.

South Dublin Guardians have accepted the tender of the A.E.G. Electrical Co. (Manchester branch) for an electric lighting installation at the Workhouse at £2,537. 4s. and £250 for maintenance for five years.

Shoreditch Lighting committee have accepted the tender of Siemens Bros. & Co. for lead-covered paper-insulated cables for the next five months' requirements at following prices: 7/16, £58 per mile; 7/14, £73 per mile; 19/14, £147 per mile. (These prices were the lowest of five quotations.)

Bournemouth Council have accepted the tender of Wm Griffiths & Co. for the supply of Belgian tramway rails at £2,904.

Country House Lighting.—For putting in an electric light installation at King's Newton Hall (near Melbourne), which is being re-built for Mr. Cecil Paget, the tender of the Melbourne & District Electric Light & Power Co. has been accepted.

South African Contracts.—An order for electrical equipment for the new air compressor station of the new Modderfontein Gold Mining Co. has been placed with the British Westinghouse Co., and includes a number of 1,000 h.p. direct-coupled three-phase induction motors.

Messrs. Siemens Bros. & Co. have secured an order for 2,277 a.c. meters and the A.E.G. Electrical Co. an order for 88 d.c. electricity meters for Johannesburg Corporation.

The A.E.G. (Berlin) have secured a contract for the supply and erection of generators and compressors for the new power station at Rosherville (Transvaal).

Storage Battery Contracts.—The D.P. Battery Co., of Bakewell, have concluded contracts for the supply of their batteries to the Councils of St. Annes-on-Sea and Naas (Kildare), the Chorlton Board of Guardians and for a number of private installations. The maintenance of these batteries for terms of years has been undertaken by the company.

The company have also secured orders for three batteries for South Africa for mining and other purposes. Specimen cells of their manufacture are being exhibited at the Buenos Aires exhibition by their agents (Messrs. Milne, Makein y Cia) of that city. The company are open to appoint additional agencies in foreign countries where they are not already represented.

Large Nuremberg Gas Engines for the Far East.—Messrs. Mitsu & Co., owners of some of the most important mines in Japan, including many large coal fields, having recognised the necessity of producing power at the cheapest rate, decided some time back to modernise the power station at their Miike mines. They have, therefore, installed two large Nuremberg gas engines of 3,200 b.h.p. each, for generating electricity.

The order for these huge engines, which are to run on coke-oven gas, has been placed with the Maschinenfabrik Augsburg-Nürnberg A.G., of Nuremberg, Bavaria (whose London office is at Caxton House, Westminster). This well-known firm (known in engineering circles as the "M.A.N.") haue a high reputation as makers of the "Nuremberg" gas engine, which has been supplied in all parts of the globe. The same firm have also installed some large gas engines in this country, among which may be mentioned those supplied to the Bargoed colliery (Wales), aggregating 6,000 b.h.p., and the gas engine plant of several thousand brake-horse-power at present being put in at the Normanby Park steel works, near Scunthorpe.

The Lilleshall Co., the M.A.N.'s licensees for the manufacture and sale of gas engines in this country, are also busy with the Nuremberg gas engine, having supplied high power engines to the Barrow Hæmatite Co. (Barrow-in-Furness). The Lilleshall Co. have recently secured orders from the United Alkali Co. (Widnes) and from Messrs. Albright & Wilson (Oldbury) for large gas-engine plants.

Sale by Auction.—Messrs. Fuller, Horsey, Sons & Cassell will sell by auction on Thursday, Sept. 22, at 11 a.m., on the premises, Montmore-street, London Fields, N.E., the goodwill of the business of the Foxcroft & Duncan Engineering Co. (Ltd.), including the patterns, drawings, &c., and also, in lots in detail, the engineers' machine tools and stock, including lathes, milling and drilling machines, motors, dynamos, &c., and the stock of arc lamp and other electrical fittings. Catalogues of the receiver, Mr. C. P. Oswald (Messrs. Bolton, Pitt & Breden), 140, Leadenhall-street, E.C., Messrs. Thorp & Saunders, 79, Salisbury House, London-wall, E.C., and of the auctioneers, 11, Billiter-square, E.C. See advertisement.

Plant for Sale.—Northampton Electric Light & Power Co., Northampton, advertise for sale two exhaust steam feed water heaters and two battery charging boosters.

Patents Development.—The owners of patents No. 23,501/1899, relating to "Improvements in vacuum table lighting," and No. 12,582/1902, relating to an "Improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Information from Messrs. Lloyd Wise & Co., 46, Lincoln's Inn Fields, London, W.C.

The proprietor of letters patent No. 28,542/1907, relating to "Electrical induction furnaces," desires to enter into arrangements for exploiting same. Communications to Messrs. J. E. Evans-Jackson & Co., 19 and 20, Holborn Viaduct, London, E.C.

The proprietors of patents No. 17,533/1908, for "Improvements in electrical accumulators" and No. 19,979/1904, for "Improvements in magnetic wheels or electromagnetic motors," desire to make arrangements for exploiting the same in this country. Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

"A.E.G. Zeitung."—The September number of this journal contains as a frontispiece an illustration of the single-phase locomotive being used on the Lotschberg Railway. Dr. Stern begins a serial on the subject of the "Distribution of Electrical Energy to a Distance." Other articles deal with "The Use of the Electric Motor in Gas Works," "The Instrument Showrooms of the A.E.G." and "Wind Driven Electricity Works."

CATALOGUES, &c.

G.E.C. Apparatus.—We have received from the General Electric Co. a number of catalogues dealing respectively with electric bells and accessories, electric heating and cooking apparatus and measuring instruments. The catalogues describe in an exhaustive way apparatus made by this Company under these heads, and the lists should be in the hands of every one having anything to do with this class of work.

Electric Bells and Accessories.—Messrs. Gent & Co., of Leicester, send us their latest catalogue which deals with such subjects as electric bells, indicators, pushes, contacts, wires, batteries and other similar apparatus. The catalogue is well illustrated and each type of apparatus is accompanied by sufficient description to make its method of working and purpose clear.

Western Interphone and Private Line Telephones.—The Western Electric Co. have issued a booklet dealing with private telephone lines, such as may be used on inter-communication systems or for domestic work generally. It is of book size and is primarily intended for the use of contractors and practical electricians. It can, if necessary, be provided with the name and address of the contractor printed upon it.

Cleat Ceiling Rose.—Messrs. Loxley & Co. have issued a pamphlet giving details of their "V.B." cleat ceiling rose, for which a number of advantages are claimed.

Burglar Alarm.—The Adnil Electrical Co. have ready a description of their "Blut" patent burglar alarm which is worked electrically and is claimed to overcome all the disadvantages inherent in this type of apparatus.

Iron and Steel Pipes.—Messrs. J. Spencer, of Wednesbury, forward a price list of the tubes, pipes, &c., made by them. These

Digitized by Google

vary from quite small sizes up to tube poles suitable for tramway and arc lamp work.

WATER-TUBE BOILERS.—Messrs. Clarke, Chapman & Co. are issuing a pamphlet which sets out the various points and advantages of the Woodeson patent water-tube boiler, which is made by them.

ELECTRICAL INSULATING MATERIALS.—Messrs. Meirowsky & Co. send a pamphlet dealing with various electrical insulating materials, including megohmite of various kinds, mica cloth and mica rubber and paper. This is made up into tubes, tape and insulating fittings generally.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during August, 1910, and (*b*) during the current year from Jan. 1 to Aug. 31, with the increases or decreases compared with the corresponding periods of 1909:—

Electrical machinery (*a*) £60,354 (increase £12,451), (*b*) £383,498 (increase £45,688); telegraph and telephone cables (*a*) £12,159 (increase £704), (*b*) £91,856 (increase £7,590); telegraph and telephone apparatus (*a*) £18,157 (increase £2,589), (*b*) £117,763 (decrease £2,846); other electrical wires and cables, rubber insulated (*a*) £17,683 (increase £8,242), (*b*) £138,078 (increase £75,889), with other insulations (*a*) £1,978 (decrease £1,614), (*b*) £19,338 (decrease £38,878); carbons (*a*) £12,212 (increase £3,745), (*b*) £90,428 (increase £5,128); glow lamps (*a*) £53,735 (increase £34,263), (*b*) £374,462 (increase £106,853); arc lamps and electric searchlights (*a*) £256 (increase £20), (*b*) £2,281 (decrease £6,845); parts of arc lamps and searchlights (other than carbons) (*a*) £8,208 (increase £2,832), (*b*) £48,400 (increase £9,685); primary and secondary batteries (*a*) £3,695 (increase £1,488), (*b*) £27,634 (decrease £1,659). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £135,528 (increase £52,768), (*b*) £976,619 (increase £155,294).

Exports.—The exports of electrical machinery, material, &c., (*a*) during August, 1910, and (*b*) during the current year from Jan. 1 to Aug. 31, and the increases and decreases compared with the corresponding periods of 1909, are as follows:—

Electrical machinery (*a*) £135,082 (decrease £9,182), (*b*) £1,026,757 (increase £52,269); telegraph and telephone cables (*a*) £437,723 (increase £395,590), (*b*) £1,467,816 (increase £990,810); telegraph and telephone apparatus (*a*) £32,430 (increase £20,693), (*b*) £132,564 (decrease £52,617); other electrical wires and cables, rubber insulated (*a*) £60,286 (increase £33,919), (*b*) £288,609 (increase £112,817), with other insulations (*a*) £40,053 (increase £18,171), (*b*) £209,999 (increase £12,794); carbons (*a*) £1,846 (increase £983), (*b*) £11,707 (increase £5,656); glow lamps (*a*) £9,641 (increase £2,473), (*b*) £82,006 (increase £33,872); arc lamps and searchlights (*a*) £3,156 (increase £1,620), (*b*) £14,178 (increase £731); parts of arc lamps and searchlights (other than carbons) (*a*) £1,709 (increase £800), (*b*) £9,741 (decrease £121); primary and secondary batteries (*a*) £10,627 (increase £6,504), (*b*) £80,663 (increase £10,486). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £640,347 (decrease £481,159), (*b*) £2,603,036 (increase £1,169,412).

BANKRUPTCIES, LIQUIDATIONS, &c.

At the London Bankruptcy Court last week the adjourned meeting of creditors of J. T. Murray (77, Gunterstone-road, W. Kensington, London) took place. Liabilities £3,212, assets £73.

Debtor has been engaged in the negotiations in connection with the Scutari Tramways concession. The receiving order was made in May, 1908, but proceedings have been adjourned from time to time to enable the scheme to be carried through. The meeting was again adjourned to March 1, 1911.

A third and final dividend (4s.) is payable at 2, Clement's Inn, London, W.C., in the liquidation of Joseph Richmond & Co. (Ltd.), 30, Kirby-street, London, E.C.

The Clarence Engineering Co. (Ltd.) is being wound up voluntarily. Claims to the liquidator, Mr. J. R. Woodley, 39-41, Wood-street, Cheapside, London, E.C.

The liquidator (Mr. W. Allnatt, 5, Lime-street, London, E.C.) of the Empire Electric Light & Power Co. (Ltd.) has been released.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

June 16, 1910.

14,534 MATHIESON. Contact device.
14,575 BOSCH. Constructing magneto-electric ignition machines for internal-combustion engines. (Date applied for, 19/7/09.)*†
14,583 MORRIS, ELLIS & MURPHY. Obtaining rapidly varying electric currents.

June 17, 1910.

14,625 ELECTRIC & ORDNANCE ACCESSORIES CO. & COLLINS. Slow-motion devices for use in connection with electric controllers, starting switches and the like.
14,626 TAYLOR. Electric filament lamps.
14,658 SOLDATENKOW. Electromagnetic device.
14,659 SOLDATENKOW. Printing telegraphs.
14,672 BAKER. Electrical transmission of photographs, drawings and the like.
14,680 PARSONS & LAW. Dynamo-electric machinery.*

June 18, 1910.

14,743 B.T.-H. Co. (G.E. Co., U.S.) Alloys for use as electric resistance conductors.
14,744 MACFARLANE. Electric transformers or converters.

June 20, 1910

14,773 TAYLOR. Limiting the flow of current on a short-circuit.
14,775 SOMERS & CROWLEY. Secondary electric batteries.
14,851 ADAMS MFG. Co. (Cutler Hammer Mfg. Co., U.S.) Controllers for electric motors.*
14,857 PODSZUS. Vapour electric apparatus. (Date applied for, 7/10/08, comprised in No. 22,827, dated 6/10/09.)*
14,859 PRESSER. Electric welding process. (Date applied for, 20/9/09.)*†
14,862 & 14,863 ALLGEMEINE ELEKTRICITATS GES. Dynamo-electric machines. (Addition to No. 13,864/04. Date applied for, 21/6/09.)*†

June 21, 1910.

14,889 RICHMOND. Depolariser for galvanic batteries.
14,912 WILKINSON. Electric heating apparatus.
14,916 CONNER & PEEL CONNER TELEPHONE WORKS. Telephone systems.
14,918 WILSON & WILSON. Electric oscillating systems.
14,946 & 14,956 ADAMS MFG. Co. (Cutler Hammer Mfg. Co., U.S.) Controllers for electric motors.*

June 22, 1910.

15,004 THOMSON. Small or pocket electric lamps.
15,018 SIEMENS BROS. DYNAMO WORKS & NEBEL. Arc lamps for use with searchlight projectors.*
15,027 MCLEAN. Supporting electric lamps and the like.
15,031 PRESSER. Regulation of the welding heat in electric welding. (Addition to No. 14,859/10.)*
15,032 PRESSER. Connection for electric welding by continuous current and the use of condensers. (Addition to No. 14,859/10.)*
15,033 PRESSER. Polarisation of fluid condensers in an electric welding apparatus. (Addition to No. 14,859/10.)*
15,037 SWEETSER & ELECTRIC SIGN & GENERAL ADVERTISING Co. Electric switch apparatus.*

June 23, 1910.

15,086 RIDINGS. Arc lamps.
15,123 POTTS. Automatic telegraphic transmitters. (Date applied for, 29/6/09. Comprised in application No. 15,167, dated 29/6/09.)*
15,134 RØDRUP. Magneto-ignition devices for internal-combustion engines.
15,139 HERING. Electric furnaces. (Date applied for, 6/7/09.)*†
15,143 KLOSTERMANN. Arc lamps. (Date applied for, 26/6/09.)*†
15,150 ENGEL. Electrical contact device. (Addition to No. 6,765/08. Date applied for, 23/6/09.)*†
15,164 THOMSON. Resisters of electric furnaces. (Date applied for, 1/9/09.)*†
15,165 THOMSON. Revoluble or oscillatory electric furnaces. (Date applied for, 1/9/09.)*†
15,166 FITZGERALD. Electric furnaces. (Date applied for, 1/9/09.)*†
15,167, 15,168 & 15,169 THOMSON. Electric furnaces.
15,170 NORTH. Alternating-current electric meters.
15,180 KRUGER. Bending filaments for electric incandescence lamps.*

June 25, 1910.

15,306 ORLING & ORLING'S TELEGRAPH INSTRUMENTS SYND. Electric transmitters.
15,318 HÖFERMANN. Disinfecting device for telephone apparatus. (Date applied for, 27/1/10.)*†
15,325 B.T.-H. Co. & PARK. Electric traction systems.

June 27, 1910.

15,343 SMITH & LARSEN. Electric controllers. (Date applied for, 30/9/09.)*†
15,365 GARFORTH & BOUSFIELD. Electric switches.
15,388 THOMAS. Control of series-wound dynamo-electric machines.
15,414 CHRISTIAN. Trolley poles in overhead electric traction systems.*
15,415 AKT.-GES BROWN, BOVERI, ET CIE. Voltage regulation of dynamo-electric altenating current machinery. (Date applied for, 10/7/09.)*†
15,417 KOHLER. Alternating current solenoids. (Date applied for, 17/9/09. Comprised in Application No. 21,249, dated 17/9/09.)*
15,422 MONEY. Electro-magnetic apparatus for the transmission of power.
15,423 NEWTON. Constant voltage generators.
15,424 HARRISON. Electric incandescent lamps.
15,425 PRITCHETT. Accumulator boxes.*
15,426 ALLGEMEINE ELEKTRICITATS-GES. Control of dynamo-electric machines. (Date applied for, 28/6/09)*†

June 28, 1910.

15,448 O'HARA. Sanitary telephone mouthpieces.*
15,482 WINTERHALDER. Cut-out switches.*
15,497 GALLETTI. Production of continuous wave trains by means of primary spark circuits. (Date applied for, 29/6/09.)*†
15,548 THOMPSON. Controller regulators for electric motors.*
15,564 MOORE. Electrical switches oerated by a vehicle passing along a railway.

June 29, 1910.

15,574 BISHOP. Locking nuts on insulator attachments of telegraph poles and for other like uses.
15,587 HOLBECH. Dynamo-electric machinery.
15,618 ANDERSON, RUSSELL & RAY. Systems for the distribution of electric energy. (Addition to No. 21,219/09.)*
15,619 LAMBOT. Automatic electric recording devices.*
15,621 SKAUPY. Manufacture of electric metal filament lamps. (Date applied for, 6/12/09.)*†
15,625 MIDGLEY & VANDERVELL. Dynamo-electric machinery. (Addition to No. 16,447/09.)
15,664 SEFTON-JONES. (Paul Prevot, France.) Electrolytic copper process.

June 30, 1910.

15,684 DEAN. Armoured or protected electric switches and fuses.
15,692 LENZ. Apparatus in wireless telegraphy, for detecting the direction of transmitting station from receiving station.
15,710 QUINT. Enclosed electric lamps of the inverted type.
15,731 CHAMPION. Electric-junction boxes and similar or other chambers.
15,734 MONTAGNA. Telegraphic and telephonic transmission of pictures. (Date applied for, 6/11/09.)*†
15,744 SOCIETE DES ETABLISSEMENTS GAUMONT. Energy relays. (Date applied for, 30/5/10.)*†
15,753 ALLGEMEINE ELEKTRICITATS-GES. Dynamo-electric machines. (Date applied for, 1/7/09.)*†

July 1, 1910.

15,770 CARTER. Dynamo-electric machines.
15,789 PECHIN. Cup insulator with centrifugal contacts for arc lamps.*
15,792 BOWYER & ANCHOR CABLE Co. Providing electric conductors with an identifying covering.
15,807 JANDUS ARC LAMP AND ELECTRIC Co. & JONES. Arc lamps.
15,836 MAHONEY. Braking systems for electric motor-driven vehicles. (Date applied for, 29/7/09.)*†
15,837 ROSENTHAL. Transmitter for submarine telegraphy and telephony. (Date applied for, 8/7/09.)*†

July 2, 1910.

15,862 HOPE. Fusible cut-outs for controlling electric circuits.
15,865 SOCIETE ANONYME FORGES DE BELLECOURT. Bogies for the rolling-stock of railways and tramways. (Date applied for, 11/4/10.)*†
15,873 BULLIMORE & COSSOR. High-tension electrical condenser.
15,879 SCHROTER. Manufacture of electric metal filament lamps. (Date applied for 21/1/10.)*†

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

2,014 WHITING. Crossings for tramway rails and the like. (Post-dated 26/8/09.)
5,777 BELL & PLETTS. Electrically heating air and other media.
9,242 HENWOOD. Optical electromagnetic speed-indicators.
11,956 WALKER. Dynamo-electric machines.
13,509 WILSON & WILSON. Spark coils. (Cognate application, 28,699/09.)
13,530 DONOVAN. Electric starting and regulating switches.
13,842 RIDINGS. Arc lamps.
13,961 B.T.-H. Co. (G.E. Co., U.S.) Electric heating devices.
14,352 GEORGI & REYROLLE & Co. Protective arrangements for electrical current distribution systems.
14,763 LAMKIN & NUNWICK. Holders for incandescence electric lamps
14,873 HOLDEN. Electric clocks.
14,980 FASSLER. Rectification of alternating electric currents and devices for use therein.
15,273 LEIGH. Suspension cables or supports.
15,287 JOHNSON & PHILLIPS & BROCKIE. Magazine electric arc lamps.
15,441 VERITY'S & PIPKIN. Construction of quick make and break electrical switch.
16,558 LAKE. ("Polyfrequenz" Elektricitäts-Ges.) Producing electrical oscillations.
16,607 CHETWYND, KELVIN & JAMES WHITE (LTD.) & CLARK. Portable magnetic compasses. (Addition to No. 21,634/08.)
16,649 WEST. Quick make and break electric switches.
17,564 B.T.-H. Co. (G.E. Co., U.S.) Rotary electric converters.
17,863 MAGGIORA & SINCLAIR. Electric motors.
19,465 DE STEFANO. Electro-magnetic device. (Date applied for, 26/8/09.)
21,021 HIGHFIELD. Installation of electrical conductors.
21,480 B.T.-H. Co. (G.E. Co., U.S.) Electrolytic condensers.
21,526 WATKINS. Insulator for supporting the current rails of electric railways and tramways.
21,564 ROYCE. Electric heaters.
21,649 BURNET & TUDOR ACCUMULATOR Co. Jointing of rails for tramways and the like.
22,029 DENEREAZ. Socket and plug for electric lamps and other apparatus utilising electric current.
22,458 KRAUSE. Metal filament lamps having filament carriers arranged elastically. (Date applied for, 10/6/09.)
23,429 MUIRHEAD & MUIRHEAD & Co. Electric telegraphy.
24,134 MANDERS. Production of continuously maintained and sustained oscillations of electricity.
26,444 MITCHELL & DUDGEON. Means for supporting overhead electric wires and cables.
26,570 DENNY. Electric tumbler switches.
26,705 KÖRTING & MATHIESEN AKT.-GES. Arc lamps. (Date applied for, 23/11/09.)
29,026 VAN RADEN. Electrical ignition apparatus for internal-combustion engines.
29,481 FESSENDEN. Wireless electric signalling. (Date applied for, 11/2/09.)
29,801 BROS. Automatic telephone exchanges.
30,093 HIBBERD. Coin-freed mechanism for electricity meters. (Date applied for, 23/6/09.)

1910 SPECIFICATIONS.

350 KRAUSE. Metal filament lamps having filament carriers arranged elastically. (Date applied for, 7/7/09, originally included in No. 22,458/09.)
722 FARRELL. Electric motor power transmission.
1,428 SIEMENS BROS. & Co. (Siemens & Halske Akt.-Ges.) Damped electrical relays.
1,482 JACKSON & SCHEIBE. Control apparatus for vapour electric rectifiers. (Date applied for, 21/1/09.)
2,377 WILLIAMS & TORTORICE. Railway rail joints
2,904 HEUTERMANN. Cross tie or sleeper for railway rails.
3,579 DUTTON & MCKENZIE & HOLLAND (LTD.) Signalling and interlocking for railways and tramways. (Addition to No. 784/09.)
5,917 SIEMENS & HALSKE AKT.-GES. Rectifier for high-tension alternating currents. (Date applied for, 28/5/09.)
6,125 SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke Ges.) Regulation of electric frequency converters.
6,168 MORRIS & BASTERT. Overhead runways.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES.

NEW COMPANIES.

GEORGE HILL & CO. (LTD.) (111,525.)—Reg. Aug. 30, capital £4,000 in £1 shares, to take over the business carried on by George Hill & Co., Manchester, and to carry on the business of electricians, engineers, manufacturers, &c. Private company. First directors, A. R. Walmsley, A. K. Walmsley and R. Barron. Reg. office, 12, Cornbrook Park-road, Manchester.

SWANN GARLAND (LTD.) (111,606.)—Reg. Sept. 3, capital £5,000 in £1 shares, to carry on the business of manufacturers of and dealers in art metal work, electric light fittings, stove grates, fenders, &c. Private company. First directors, T. Swann Garland (permanent managing director, subject to holding 500 shares) and M. D. Cooke.

UNITED LIGHTING & MAINTENANCE CO. (LTD.) (111,517.)—Reg. Aug. 29, capital £2,000 in £1 shares, to take over the business of electricians, &c., carried on by S. Mundler as the National Lighting Co. Private company. First directors, M. Kaiser, S. Mundler and J. W. May. Reg. office, 35, Cock-lane, London, E.C.

WILLIAM H. SAYER & CO. (LTD.) (111,590.)—Reg. Sept. 2, capital £500 in 10s. shares, to take over the business of an electrical and mechanical London and export merchant carried on as W. H. Sayer & Co. Private company. W. H. Sayer is first director. Reg. office, 10, New-street, Bishopsgate, London, E.C.

W. V. WAITE & CO. (LTD.) (111,537.)—Reg. Aug. 30, capital £1,000 in £1 shares, to carry on the business of electrical, mechanical, hydraulic, civil, railway, consulting and general engineers, agents, &c. Private company. First directors, W. Waite, C. P. Waite and W. V. Waite (managing director).

STATUTORY RETURNS.

CHILI TELEPHONE CO. (LTD.)—According to return dated July 28 capital is £250,000 in £5 shares. 44,000 shares taken up. £220,000 paid. Mortgages and charges, nil.

CHILIAN ELECTRIC TRAMWAY & LIGHT CO. (LTD.)—In return dated July 21 capital is £1,150,000 in 500,000 ordinary and 650,000 preference shares of £1 each. All shares taken up. £650,000 paid on the preference. £500,000 considered as paid on the ordinary. Mortgages and charges, £433,400.

ELECTRIC CONSTRUCTION CO. (LTD.)—Return dated July 28 gives capital as £400,000 in 150,000 preference and 50,000 ordinary shares of £2 each. 112,100 ordinary and 31,390 preference shares taken up. £2 per share called up on 2,100 ordinary and 18,245 preference. £40,690 paid. £246,290 considered as paid on 110,000 ordinary and 13,145 preference. Mortgages and charges, £210,000.

MADRAS ELECTRIC SUPPLY CORPN. (LTD.)—Return to Aug. 3 gives capital as £400,000 in £5 shares. 60,000 shares taken up. £300,000 paid. Mortgages and charges, nil.

UNITED RIVER PLATE TELEPHONE CO. (LTD.)—The capital in return dated Aug. 2 is £1,000,000 in 150,000 ordinary, 40,000 preference and 10,000 unissued shares of £5 each. 150,000 ordinary and 40,000 preference shares taken up. £5 per share called up on 134,000 ordinary and 40,000 preference. £870,000 paid. £80,000 considered as paid on 16,000 ordinary shares. Mortgages and charges, £300,000.

MORTGAGES AND CHARGES.

F. BURKS & CO. (LTD.)—Issue on July 8 of £480 debentures, part of a series of which particulars have already been filed.

WILLIAM COATES & SON (LTD.)—Deposit of deeds on Aug. 19 securing all monies due to and to accrue from the company to holders, charged on premises in Castle-street, Belfast.

IMPERIAL LAMP WORKS (BRIMSDOWN) (LTD.)—Issue on Aug. 18 of £25,000 debentures, part of a series of which particulars have already been filed.

VAN RADEN & CO. (LTD.)—Mortgage, dated Aug. 15, to secure £1,850, charged on freehold factory, land and premises at Coventry. Holder, C. W. Hill.

CITY NOTES.

MEMORANDA (Sept. 8).—**Bank rate 3 per cent. (since June 9, 1910) Price of silver,** 24⅛d. per oz. Consols 80⅜—80⅝ for money; 80½—80¾ for account. **Consols Pay Day, Oct. 5; Stock and Shares Continuation Days,** Sept. 13 and 27; **Ticket Days,** Sept. 14 and 28; **Pay Days,** Sept. 15 and 29; **Mining Shares Carry Over Day,** Sept. 12.

PRICES OF METALS (London).—*Copper*, cash, 55⅜; three months, 56¾. *Lead*, English, 12¼—13; foreign, 12½—12⅝. *Spelter*, 22⅛—22⅜ *Tin*, English, 156½—157½; foreign cash, 166; three months, 157⅜. *Iron*, Cleveland, cash, 49/6, three months, 50/3.

AMALGAMATION OF CANADIAN ELECTRICAL COMPANIES.—It is announced that the Montreal Street Railway Co. and the Canadian Power Co. have been amalgamated. The new company will have a capital of $60,000,000.

CANADIAN GENERAL ELECTRIC CO.—A dividend of 1¾ per cent. has been declared on the common stock for the quarter ending 30th inst.

DAVIS & TIMMINS (LTD.)—An interim dividend of 6 per cent. on the ordinary shares, for the half-year ended June 30 has been declared.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have appointed Sept. 9 a special settling day in scrip, fully and partly paid, for £300,000 6 per cent. Government guaranteed loan of the *Electric Light & Power Co. of Cochabamba*. The committee have been asked to grant quotations to a further issue of £50,000 4½ per cent. first mortgage prior lien gold bonds of £100 each of the *Montreal Water & Power Co.*, £250,000 5 per cent. first mortgage debentures (in lieu of the scrip) of *Vera Cruz Electric Light, Power & Traction (Ltd.)*, and a further issue of £200,000 4½ per cent. perpetual consolidated debenture stock of the *Winnipeg Electric Railway Co.*

YORKSHIRE ELECTRIC POWER CO.—At the meeting on Tuesday the chairman (Mr. A. G. Lupton) said that it was interesting to compare the past half-year with the corresponding half-year of 1903. In the two years the total receipts for the six months had increased from £8,698 to £16,675, and the gross profit had grown from £1,249 to £4,950. It was to the increasing ratio of profit to revenue that they looked to put the company on a dividend basis. Supply had been given for several months to a large colliery in Castleford for hauling, pumping, ventilating, lighting, &c. Negotiations were proceeding with colliery proprietors both in that and other portions of the company's area, and they anticipated a largely increased demand for these purposes in the near future. Castleford was also providing a number of other customers anxious for their supply. An overhead line was being carried to the western portion of their area from Brighouse to Sowerby Bridge, where the Distribution Company was being pressed for a supply, and where some important contracts had already been made, including a considerable supply to a large cotton mill now being built there. A further extension was also being proceeded with in the vicinity of Barnsley, where a large colliery would shortly be taking energy. During the half-year further connections had been made to the mains laid or erected before the present year. In the case of a large mill in the Dewsbury district, owing to the total collapse of one of the main mill engines the company had been called upon for an emergency supply. The damage was so considerable that many months would have elapsed before the engine could have been repaired or renewed, but a partial supply was given within a few hours, and some hundreds of horse-power of motors were connected, and the whole mill running as before in less than a fortnight, greatly to the relief of both employers and workpeople.

NOTES.

Rail Corrugation.

ALTHOUGH no important pronouncements or new theories have appeared of late in regard to the origin of corrugation on tramway rails, the subject is of necessity uppermost in the minds of tramway managers, many of whom have adopted the expedient—a temporory one it is to be hoped—of grinding out such corrugations where they have become very pronounced. The origin of the trouble, which is probably due to several contributory factors, can be ascertained with most certainty by careful compilation and comparison of the results obtained in different undertakings. Early attempts in this direction led to no very satisfactory conclusions, the evidence being so conflicting that widely divergent theories were inevitable. The fact that in many undertakings corrugation was only just becoming noticeable, and that on routes with an infrequent service of cars the absence of corrugation was not conclusive evidence, increased the difficulty and resulted in theories which further experience showed to be untenable. As we have mentioned, it is by the systematic sifting of evidence that the correct explanation of the phenomenon is to be found, and in this direction much useful work is being done by a committee of the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local. The more important answers to the *questionnaire* recently sent out by the Union will be found elsewhere in this issue, together with a report by Herr BUSSE, chief engineer of the Berlin Tramways, on the replies received. This report, which should prove of considerable interest to engineers generally, was presented at Brussels at the recent biennial meeting of the Union. Of the 75 towns from which replies were received, only 13 reported comparative freedom from corrugation.

A COMPARISON of the replies with those received two years ago (published in THE ELECTRICIAN of October 9, 1908) gives additional support to the theory that the primary cause of corrugation is to be found in the quality of the metal used for the rails and in the rolling process adopted. Herr BUSSE considers the evidence conclusive in support of these being the chief factors in the phenomenon. An interesting case in point is cited in which rails rolled in different years were laid alternately along the same route; and it was found that the rails rolled in one particular year corrugated much more than the others. Other factors, however, have to be taken into consideration, such as the construction of the rolling stock, the method of propulsion and the track foundation. These appear to influence very considerably the intensity of the corrugations and the rate at which the latter develop. In view of the increasing use of methods of rail welding, it is interesting to notice the experience at Magdeburg. This is to the effect that corrugation develops very rapidly and with great intensity on rails of great length or where rails are welded together. Further evidence on this point should prove valuable, and engineers will be anxious to know if experience in other towns supports that at Magdeburg. The advantages of welding are so many that it is to be hoped a greater tendency to produce corrugations will not have to be set against the smooth running provided by a continuous rail. Although attention hitherto has mainly been centred on the track, it must not be forgotten that corrugation is making its appearance else-

Digitized by Google

where, about half the number of undertakings having experienced it in connection with their trolley wires and eight on their tyres, as well as on the rails.

Science and Industry.

In another column will be found an abstract of a Paper on "The Relations of Science to Industry and Commerce," read by Mr. R. Blair at the recent meeting of the British Association. It will be remembered that Mr. Blair is Education Officer to the London County Council, and is therefore interested in education in all its phases. The Paper is of more than usual interest because it includes the opinions of a large number of persons concerned, including students, professors, employers and consuls. Near the beginning of the Paper Mr. Blair refers to the importance of influence, a case being cited in which a well qualified man was only able to obtain a post through influence, but made rapid headway, justifying the confidence placed in him, as soon as he obtained a position. We think, however, that this must be a very isolated case. Generally speaking, we doubt if influence counts for very much, and more often than not a letter of introduction is viewed with suspicion. On the other hand, influence may be important with committees, and we quite admit that sometimes a little interest may make just the difference. But given a good man without, and an inferior man with, a letter of introduction, we think in ordinary commercial work the latter would not stand the best chance. Of course, this does not apply to the proverbial nephew of the managing director.

A point that must be regarded as unsatisfactory in the educational situation is the large proportion of students who take up teaching as a profession. Obviously the teacher who has been through the mill and has earned his livelihood at electrical engineering is better qualified to teach, from the engineering point of view, than a man who proceeds to teach as soon as he has passed through his college course. Another point to which Mr. Blair refers is the attitude of the employer towards the technical student. This is certainly much more favourable than it used to be, and probably a good deal has been gained by the professor realising what are really the needs of the employer as well as by the employer realising that there are considerable benefits in technical education. Nevertheless, we do not suppose that the college course has yet been standardised to the greatest advantage. As illustrating want of completeness we may refer to the question of cost in engineering: this is persistently neglected in many educational institutions, as is strongly emphasised in one quotation, and we hope that the necessity of bearing this important matter in mind will be taken to heart by those of our readers who are in a position to effect some reform.

A Useful Accelerometer.

One of the most interesting Papers read at the recent meeting of the British Association was that by Mr. H. E. Wimperis, an abstract of which we publish in this issue. By means of an extremely simple and ingenious piece of mechanism Mr. Wimperis has opened a way for the investigation of an enormous number of important problems. At the present time the Automobile Club are carrying out experiments on cars by means of a moving road carried on revolving rollers, an apparatus both costly and cumbrous; the new accelerometer will do much more than this machinery in a fraction of the time and at a trifling expense. As Prof. Perry remarked, it is an excellent example of what can be accomplished by the application of commonsense to scientific knowledge. Experiments with the new instrument on tramcars and electric railway trains should yield some interesting results, and we look forward to hearing a great deal more about the accelerometer before many months have past

Obituary.—V. A. H. McCowen.—We regret to record the death, which took place at Bath on the 8th inst., of Mr. Victor A. H. McCowen, late electrical engineer to Salford Corporation, and of the Gables, Higher Broughton. Mr. McCowen was only 44 years of age, and was appointed chief electrical engineer at Salford in March, 1907, in succession to Mr. C. D. Taite, who resigned. Prior to that time Mr. McCowen had been for many years city electrical engineer at Belfast, superintending the carrying out of the original gas engine scheme drawn up by Sir A. B. W. Kennedy in 1894. From the completion of this scheme until 1907 Mr. McCowen also acted as consulting engineer to the Belfast Corporation, designing the existing works, which supply current both for lighting and traction. He also acted as consulting engineer to the Urban District Council of Ballymena and other public bodies. In the early days of electric lighting Mr. McCowen was connected with the Sydenham District Electric Supply Co. (the first high-tension continuous-current system with rotary transformers in the United Kingdom) and the Killarney Electric Light Co. Within twelve months of his appointment as borough electrical engineer of Salford he had the misfortune to lose his wife. He felt this keenly, and shortly afterwards became ill, suffering from neuritis, which speedily developed into sarcoma of the spine. After being away from business for short periods, he left Salford to take up residence in a medical home at Bath, where he died, as mentioned above, last week. In April of the present year his resignation of his position at Salford was accepted by the Council with great regret.

William Finlay.—We also regret to record the death of Mr. William Finlay, of Edinburgh, who was president last year of the Electrical Contractors' Association. This occurred at his father's residence in Edinburgh, on the 7th inst. The immediate cause of death was a block in one of the arteries of the brain; this caused heart failure, and death took place 26 hours after the first symptom. Deceased was 38 years of age, and leaves a wife and family. The funeral took place on the 12th inst.

C. A. Brereton.—We also regret to record the death of Mr. C. A. Brereton who was for many years a partner of Sir John Wolfe Barry. He was connected with much railway and dock work, including the Llynvi and Ogmore Railways and Portcawl Docks, the Lewes & East Grinstead Railway, and the Inner Circle. In association with Sir John Wolfe Barry, he designed the Barry, Middlesborough and Surrey Commercial Docks and the new Kew Bridge. He also carried out work on many other railways, including the Metropolitan, Metropolitan District and the Piccadilly Tube.

N. J. A. Boex.—We regret to learn of the death on the 7th inst., after a short illness, followed by an operation in London, of Mr. N. J. A. Boex, London Superintendent of the Direct Spanish Telegraph Co. Mr. Boex was only taken ill on the night of the 4th. His remains were cremated at Golder's Green on Saturday last. Mr. Boex was one of the original members of the staff of the Submarine Telegraph Co., and entered the Direct Spanish Telegraph Co.'s service at Falmouth in 1881.

Electrical Exhibition at Olympia in 1911.—We understand from the International Trades Exhibitions (Ltd.), who are taking up the work of organisation, that definite arrangements have now been made for the holding of an electrical exhibition at Olympia next year from September 23rd to October 21st. The exhibition will be promoted by the National Electrical Manufacturers' Association, as at Manchester.

Martyrs to Science.—Another alarming case of X-ray dermatitis has to be recorded. Mr. Ernest Wilson, one of the radiographers at London Hospital, has undergone a sixth operation, and has been compelled to retire from the field of active work. There are many hundreds of persons able to carry on their daily avocations who have to thank Mr. Wilson and other pioneers for their good health and strength. What is especially satisfactory is that the experience gained in the early days has been put to the best account, and the great risk has not now to be run by men who carry on this work.

Regulations for Electricity Supply in France.—According to the Paris correspondent of "The Times," a decree recently promulgated sets forth the conditions which must be observed in connection with the distribution of electric power when the lines touch public property at any point or pass in proximity to telegraph or telephone wires. This decree is in substitution of one that was promulgated in 1908, at the time when Government control over suppliers of electric power was being organised in a methodical manner. Certain of the rules then laid down have been shown by experience to be incompatible with the requirements of commercial operation, while others have proved ineffective as regards the public safety which they were designed to secure. The new decree is the result of exchanges of views between those engaged in the industry and the engineers which the State has charged with its control. The decree divides electrical supply systems into two classes. The first contains those in which, for continuous current, the voltage does not exceed 600 between the conductor and the earth, or for alternating current does not exceed 150 volts. The other class includes those supply undertakings that work with higher voltages. When a supply system of this second class serves several centres the undertaker is put under the obligation of establishing direct communication between each of these centres and the central station, and of providing an arrangement by which the current may be cut off from any of them whenever necessary. The insulators used for systems of this class must, if the voltage is less than 10,000, be tested to a pressure three times the normal, while if it exceeds 10,000 volts they must be tested at 30,000 volts plus twice the excess of the working voltage above 10,000 volts. Conductors for both classes must be placed at least 6 metres above the ground, and those for the second class 8 metres when crossing a public road. Underground conductors must be protected mechanically against damage, and if they are placed in a metallic conduit they must still be insulated as carefully as if they were laid directly in the soil. In the case of supplies intended for traction purposes the following regulations are among those laid down to prevent stray currents :—The conductivity of the track must be maintained as high as possible, and in particular the resistance of each joint must not exceed that of 10 metres of rail; those in charge of the line must periodically test the conductivity and enter the results in a register which is to be open to the inspecting officers; at places where there are points or crossings special precautions must be taken to maintain the conductivity, and where the track passes over metallic structures it is to be insulated electrically so far as is possible. Finally the decree states the conditions which must be observed when conductors, either overhead or underground, cross roads and railways. On the whole, our contemporary remarks, the new regulations seem much more liberal and less exacting than the old ones.

Cable Interruptions.	Date of Interruption.
Assab—Perim	July 8, 1909
Malta—Tripoli	April 20, 1910
Reunion—Mauritius	May 20, 1910
Latakia—Palura	May 26, 1910
Obock—Djibouti	June 24, 1910
Cape St. James—Doson	Sept. 9, 1910

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. Wichi Torikata contributes an article on "Commercial Wireless Telegraphy in Japan," and describes the detectors which are there used, particularly the Teishinsho system.

At a recent meeting of the Union Internationale de Tramways et de Chemins de Fer d'Intéret Local a lengthy report was submitted on rail corrugation. This we give in abstract.

Mr. E. W. Cowan's Paper on "The Price of Electricity," read before the British Association, is concluded in our present issue.

We give abstracts of a number of Papers which were read at the meeting of the British Association last week, including "Utilisation of Solar Radiation and Wind Power," by Prof. R. A. Fessenden; "The Relations of Science and Industry to Commerce," by R. Blair; "The Laws of Electro-mechanics," by Prof. S. P. Thompson, F.R.S.; and "On the Use of an Accelerometer in the Measurement of Road Resistance and Horse-power," by H. E. Wimperis. We deal with the first of these in our Leading Article.

A letter has been issued by the Electric Supply Publicity Committee setting forth certain facts in relation to the position of electric street lighting in London.

The British Electrical Federation are to be congratulated upon their successful exposure of gross frauds to which electric tramway undertakings are particularly liable.

A proposal to acquire the National Telephone Co.'s undertaking in Jersey is being considered by the Public Works Committee of the States.

A further conversion of public gas lamps to electric lighting is being made at Poplar by which a saving of 6s. 8d. per lamp per annum is assured.

Edinburgh Corporation have decided to put down additional plant at Dewar-place at a cost of £45,000.

Arbitration.—Mr. Archibald Read this week commenced hearing arguments and evidence in the arbitration to decide whether the consent of Torquay Corporation to the substitution of the overhead for the Dolter surface contact system of traction on certain tramways is unreasonably withheld.

Loans for Electricity Supply.—At the L.G. Board inquiry last week into the application of Colwyn Bay Council for sanction to borrow £2,300 for cable extensions, the inspector, Mr. H. Ross Hooper, made an interesting statement as to the policy of the Board in regard to loans.

INSTITUTIONS AND SOCIETIES.

Institute of Metals.—The autumn meeting of this Institute will be held at Glasgow from September 21st to 23rd, both dates inclusive. A reception will be held by the Lord Provost of Glasgow at the Council House, George-square. The meetings will take place in the Lecture Theatre of the Natural Philosophy Building of the University of Glasgow.

Association of Engineers-in-Charge.—At the annual general meeting, which was held under the chairmanship of Mr. A. E. Penn, it was shown that the affairs of the Association were in a very satisfactory condition. Capt. H. Riall Sankey was elected president for the ensuing year.

ARRANGEMENTS FOR THE WEEK.

MUNICIPAL TRAMWAYS ASSOCIATION.

WEDNESDAY, September 21st.

11 a.m. Meeting in the Council Chamber, Town Hall, Bradford. Presidential Address by Mr. C. J. Spencer. Paper on "The First Decade of Municipal Tramway Working," by Alderman S. Flint.

3 p.m. Paper on "The Comparative Durability of Brake Shoes and Tyres," by Mr. J. W. Dawson.

THURSDAY, September 22nd.

10:30 a.m. Meeting in the Council Chamber, Town Hall, Bradford. Paper on "Tramways in Relation to Town Planning," by Mr. A. Baker; and Report on "Lubrication of Car Bearings," by Messrs E. Cross, R. L. Acland, P. J. Pringle and T. R. Smith.

FRIDAY, September 23rd.

10 a.m. Annual General Meeting in the Town Hall, Bradford.

SATURDAY, September 24th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

5:15 p.m. Reception at the Engineering Exhibition, Olympia. Lecture at 7:45 p.m. on "Wireless Telegraphy, its Maritime Importance," by G. Langler Bullocke (by special permission of Mr. Marconi).

RAIL CORRUGATION.*

BY A. BUSSE.

Summary.—In this report the author points out that the conclusion that rail corrugation is due primarily to weaknesses in the rail metal or to peculiarities in the rails caused by the rolling is now being generally adopted. A summary of the opinions received from the members in answer to the *questionnaire* on this subject is given and the conclusion is again arrived at that in the rails is to be found the primary cause of this phenomenon.

Rail corrugation, which develops from year to year in ever-increasing proportions, causes not only an excessive wear of the wheels and rails, but is also a source of great annoyance to tramway managers from the secondary phenomena which accompany it. Where corrugation exists the track wears rapidly, the rails fall away from the paving and the vibrations that are set up soon tend to destroy the foundations, especially when asphalt or wood paving is used.

In the report presented at the Milan congress in 1908 it was remarked that corrugation might be due to something in rail metal itself, while in a report made by M. Petersen, of Dortmund, the same conclusion is also arrived at. Some further researches of M. Petersen are given in an appendix to the present report.

A very interesting result is provided by these tests. Rails, which were rolled in different years, were placed on a certain section of line so that the years of manufacture alternated, with a view to discovering whether rail corrugation was the same for all rails. As a result, it was found that rails rolled during one particular year showed much more corrugation than the others. All the others were, in fact, practically untouched. This anomaly is a good proof that the rolling and the nature of the metal may be considered as a principal cause of corrugation.

A similar result has been observed on the Prussian State Railways. A section over which heavy traffic was worked was made up of rails from two different rolling mills. These rails were placed in no particular order. But it was noticed that the rails from one of the mills showed a very large amount of corrugation, while those from the other were not touched. This seems to indicate conclusively that the phenomenon may be attributable to the quality of the metal and to the way in which the rails are manufactured.

Nevertheless, it would be well to carry out tests and observations on the construction of the rolling stock, on the method of propulsion and on the track foundation. It is, in fact, certain that these different factors have an influence on the appearance of the corrugations, especially on their intensity and on the speed with which they appear. This opinion was expressed at the Munich conference.

All these phenomena show that corrugation cannot be attributed to a single cause, but that it is the result of a blending of several factors, some of which are direct and others secondary causes. Certain methods of constructing the rolling stock cause corrugation on the rolling surface, if there exist certain conditions in the quality of rail or tyres, or in the track foundations.

The *questionnaire*, which has been addressed this year to the members of the Union, was answered by 75 members. Sixty-two of these noticed corrugation in a more or less pronounced way on their systems. Thirty-eight noticed it on their trolley wires, and eight on their tyres.

A number of the more important answers are then given in the report. Abstracts of these are set out below:—

Amsterdam.—Corrugation has been noticed wherever the flanges of the wheels are pressed against the head of the rail. It has not been noticed on curves of small radius where the rolling surface is much worn or the speed is low. The length of the corrugations increases with the speed. It is considered that the kinetic energy of the cars is primarily responsible for the phenomenon. On straight runs, too, the flange of one wheel hits the rail head and the whole car tends to lean over to that side. The axis of the car then takes up an oblique position to the direction of motion and this obliquity increases with the narrowness of the gauge. The wheel, whose velocity of rotation has been decreased by the lateral blow, endeavours to maintain a linear velocity corresponding to the kinetic energy. It is therefore submitted to a force of translation, while the rail itself begins to vibrate. As a result, periodic changes in the friction between wheel and rail are set up, and these changes may, it is considered, cause corrugation. On curves the phenomenon is similar, the car tending to run tangentially and thus giving a motion of translation to the wheels, while the speed of rotation tends to decrease owing to the friction, with the result that slipping occurs and vibrations are set up. Tests on this question are still being made in Amsterdam for different gauges, speeds and wheels, but it seems certain that the transverse component of the kinetic energy both on curves and on straight runs gives rise to vibrations in the rail.

Augsburg.—There is no corrugation on this system, but it is thought that, as this phenomenon does not appear on steam railways, it must be due in the first place to the geared drive employed on tramways, though high speed and difference in the quality of the rail are favourable to its propagation. The reporter, however, points out that corrugation has been noticed on steam railways and that this opinion is therefore untenable.

Bordeaux.—The opinion is expressed that the method of driving causes the wheel not only to hammer the rail, but also to slip along it, thus giving rise to a displacement of the metal and hence corrugation. This slipping is, in fact, they consider, the principal cause of corrugation. It occurs both on curves and on straight runs. On the latter it is due to the different length of paths which must be traversed by two wheels fixed to the same axle, while in the former it is due to the different rolling diameters caused by the horizontal motion of the car. Experiments on this point have shown that variations in the rolling diameters correspond with these horizontal movements and that the variations which they set up in turn in the rails cause corrugation. Corrugation only exists where slipping takes place. It is therefore caused by slipping and by suppressing this effect the production of corrugation can be avoided.

Two cars fitted with an arrangement by which the slipping of the wheels on the rails can be avoided have been placed in use at Bordeaux, the idea being to make the wheels on the same axle independent of one another. One of the wheels is keyed to the axle, while the other is fixed to a sleeve, which is loose on the axle. In the case of a trailing axle this sleeve simply moves backward and forward between two flanges so that the distance apart of the two wheels may remain the same. In the case of a motor axle a differential gear similar to that used on motor cars is employed. It is placed inside the first gear wheel, which is usually keyed to the axle and which instead now becomes loose on it. It is intended to introduce this arrangement on all the cars in Bordeaux.

In their answer to the *questionnaire* this company expressed the opinion that the composition of the rail metal has but a secondary effect on corrugation. This opinion cannot, in the reporter's opinion, be sustained. As regards horizontal movements it is thought that, as these are decreased, corrugation will be decreased. Attempts should, therefore, be made to reduce these movements as well as the conicality of the rails, which is not of great importance in tramway working. An elastic foundation may diminish corrugation.

Brussels state that on their system rail corrugation is general, especially on curves of large radius—where it occurs even when the traffic is small—on grooved rails, where the slot is used, and on ordinary tracks using grooved rails, where the quality of the soil or paving leaves anything to be desired. In some cases corrugation disappeared after the track had been rebuilt with transverse wooden sleepers. It has not been noticed on tracks where Vignoles rails are used, and did not appear at all until some years after the adoption of electric traction. According to the statement of this undertaking its appearance seems to have coincided with the abandonment of the Bessemer process for the Thomas process in the majority of steel works.

Dresden consider that corrugation is an effect of friction, and that its production and development is dependent on a number of circumstances. The method of rolling need not necessarily be the premier cause, while the employment of an elastic road bed, such as wooden sleepers, almost completely prevents its appearance. Its production seems to depend upon the reaction between the moving and the stationary masses constituting the track.

At *Ekaterinoslaw* corrugation has not yet been observed on their lines. They consider this to be due to the fact that their rails are of extra hard steel. The reporter, however, remarks that in Berlin corrugation has been noticed on rails made of very hard manganese steel where these have been used in places with heavy traffic.

At *Barmen-Elberfeld* the phenomena of corrugation has been noticed in places where the road is paved, but especially where the soil has been disturbed by the laying down of drains, electric light mains and gas pipes, but the reporter points out that the phenomena appeared on new rails immediately after they were placed in service and may be attributed without any doubt to the nature of the metal used.

* Abstract of a report by Herr Busse, chief engineer of the Berlin tramways, on the replies received by the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local in response to the *questionnaire* sent out to the members, presented at the biennial meeting at Brussels (1910).

Digitized by Google

At *Glasgow* it is thought that the phenomena could be avoided by coupling together the two motor axles by a crank, as is done on steam locomotives, so that both motor wheels would run at the same speed.

Hanover express the view that rail corrugation is due in the first place to the insufficient strength of the rail metal in relation to the force imposed upon it by heavy traffic. The phenomena apparently appears more rapidly when the rails are rigid, when they are not covered in by pavement, and on curves of large radius. These conditions are, however, not primarily responsible for the production of rail corrugation, but rather accessory causes which only intervene when the rails are not sufficiently strong.

Helsingborg have observed that when corrugations occur on straight sections the waves commence at the joints and diminish progressively in both directions. On the other hand, on curves the corrugations appear uniformly on the outer rail. This company consider the principal causes of corrugation to be: too rigid or elastic foundations, a car too rigidly hung, the rolling surface at the joints not perfectly flat, and the bad effect of places where corrugation already exists. They also indicate as a possible cause the gyroscopic effect created by the high speed at which the motor armatures run.

Cairo have especially noticed corrugation in places where the street is treated with asphalt and where, therefore, the tracks are less elastic. The waves are generally more numerous and smaller in such asphalted streets than in streets where macadam is used. The hardest rails show the shortest waves.

On the other hand, *Copenhagen* point out that corrugation occurs most often on macadam, less on asphalt and "English paving," and least of all on ordinary paving. The breadth of the wave seems to be greatest at places where the speed is highest. This undertaking seems to think that corrugation is due to laminations produced by the rolling action, but a longitudinal section tested with acid did not show any modification in the structure of the rail. Tests also showed that the hardness of the rail increases as time goes on, even on rails exempt from corrugation, and this is also considered to be due to the cold rolling. An increase in the width and length of the surfaces subjected to rolling occurs from the same cause.

At *Leipzig* it is considered that corrugation is due to a lack of homogeneity in the construction of the metal. This opinion is based on the fact that corrugation only occurs at certain places on the system and only on a part of the rail. If corrugation depended on the rolling stock it would be much more general, because, as a matter of fact, conditions under which vehicles operate are the same on all parts of the system.

At *Lyons* a number of different rails have been used and corrugation has been noticed more or less on all of them. In the opinion of this undertaking it is to be attributed to the quality of the metal and to the methods used in the manufacture.

At *Madrid* corrugation has been noticed, especially on the hardest rails. It occurs with the same frequency on tracks on elastic foundations as on those on rigid foundations, but it occurs less on single tracks over which the cars run in both directions. This is explained by the fact that one effect wipes out the other.

At *Magdeburg* it has been noticed that the phenomenon occurs very rapidly and with great intensity on rails of great length or on lengths of rails which are welded together. It is supposed that the tension generated in the rails by the welding causes them to rise up, thus favouring the production of corrugation. Corrugation appears more rapidly on hard than on soft rails.

Munich consider that the hammering of the rails, caused by the rigid coupling of the two wheels on the motor axles is sufficient to create corrugation. The propelling movement of the wheels is never uniform and they are thus made to jump along. The reporter remarks that if only one primary cause is to be allowed for rail corrugation a number of secondary causes cannot be admitted when the primary cause does not exist; in other words, that rigid coupling of the wheels will have to be abandoned. It should, however, be pointed out that Munich consider that unsurmountable technical difficulties prevent the realisation of this idea.

Nuremburg-Furth observe that corrugation is only produced at places where the traffic is very heavy. It generally begins quite close to the joint, and was not noticed formerly when the rolling stock was much lighter than it is now, although the rails were much less strong and of softer metal. This undertaking has noticed traces of corrugation on new rails coming direct from the rolling mill.

Vienna are not able to distinguish between the direct causes of corrugation and those which are rather a consequence of those direct causes. The shape of the rail profile has a particular influence on the development of the waves of the rolling surface. This circumstance might, it appears, be a primary cause. This undertaking base their remarks on observations made on their system of the way in which three different types of rails behave on considerable lengths of track. These rails are the grooved rail, through which the current is collected on conduit systems; the Hartwich rail, a modification of the Vignoles rail, which has a web of great height with a corresponding check rail, and the ordinary grooved rail. It is a remarkable thing that the first rail did not show any signs of corrugation, the second rail showed it but rarely and the third very frequently. The first two types of rails were nearly always of the same quality. Their superiority appears to be due to a better arrangement of the rolling surface, which would be facilitated by the shape of the Vignoles rail. The method of foundation has also some influence. These two kinds of rails may, in fact, be considered as of equal value. The Hartwich rails rest simply on gravel, whilst the others are fixed on cast-iron plates placed at equal intervals. The slotted rail seems to be superior to the Hartwich rail as regards corrugation, and this is probably due to the type of foundation used. An important cause of corrugation seems to be that, at starting and when the brakes are being used, the wheels do not turn uniformly, but are submitted to a partial sliding and to vibration at the same time. This sliding and simultaneous oscillation of bodies in contact (wheels and rails) is sufficient to give rise to corrugation or to phenomena of the same kind. It is this which has been observed, for instance, on the platforms over which the rails are drawn after leaving the rolling mill. It should be remarked that in these two cases there are no complex circumstances and that corrugation is produced just as well when the bodies submitted to skidding action and oscillations are of the same kind as when they are of a different nature; for instance, trolley bow and overhead conductor—that is, aluminium on hard copper.

It may be added that the majority of members not cited above considered the following as principal causes of rail corrugation: The nature of the rail metal, the methods used in rolling and the sliding movements of the cars.

The importance of the sliding movement, as regards the displacement of the metal and the production of corrugation which is the consequence, is shown by some results obtained at Berlin on tracks using a "third rail" where the speed is rather over 30 miles an hour. The pressure of the shoe is about 44 lb. and the displacement of the metal is nearly always visible on the third rail, while the running rails are often free from corrugation. When the rolling surface, on the other hand, is not quite flat, the metal, however hard, cannot resist the sliding action of the wheels, and corrugation and breaking up of the rails is the result.

As an example of this we may quote a station on the Berlin Elevated Railway where trains are braked and where nickel steel rails with a strength of 44½ tons per square inch, Bessemer steel rails with a strength of 50½ tons per square inch, and manganese steel rails with a strength of 76 tons per square inch have been put down for testing purposes. At the present time, while the Bessemer rails are but slightly corrugated, both the others showed corrugation quite soon after being placed in service. This is the more remarkable as Vignoles rails, which generally wear very well, are used.

As regards corrugation on the trolley wire, it seems to appear principally at places (1) where the acceleration is great and consequently the friction between collector and wire is submitted to continual variation; (2) where the trolley wire for short lengths is particularly restrained and where, in consequence, it is especially rigid, for instance, at the points of support, under bridges and in tunnels; (3) where the wheel does not move uniformly, owing to defective lubrication; and (4) where the existence of corrugation has been noticed on the wire ever since it was placed in service and where inequalities in the rolling surface of the rails exist, so that the cars and collecting apparatus are subjected to vibrations. Glasgow mention that trolley wire corrugation has not been noticed since they removed the rail corrugation by means of an emery wheel.

Tyre corrugation has only been noticed by a few tramway authorities. At Bale it has only been noticed on trailers. This is attributed to the variation in hardness of the tyre metal, to the formation of flats on the rolling surface by too energetic braking and to inequalities in the rail surface. At Dresden corrugation with waves corresponding with the division of the gear teeth has been noticed. At Frankfort the tyres often show very decided corrugations, though this is most certainly due to the nature of the metal.

From the answers received to questions on rail corrugation, it appears that recent observations and tests have added nothing, or very little, new to the conclusions formulated at the Congress at Munich in 1908. An important matter may, however, be noted: exhaustive researches prove that the rail metal contains in itself the "bacillus" which leads to rail corrugation. Further, sideways

Digitized by Google

movements, wheel slippings and other causes have been abundantly shown to favour its production. The influence which these movements were shown to have has further incited members to suppress or diminish these phenomena. Work in this direction has already been taken up.

Attention may also be called to another important matter. Rails embedded in concrete on wooden sleepers, and grooved rails fixed to metal chairs on conduit system where the rails are firmly fixed to the foundation, are much less affected by corrugation than long lengths of rails obtained by welding or by the employment of the Melaun joint. It may be supposed that the tension generated in these rails causes them to rise, thus favouring the production of corrugation. It would be interesting to lay down rails on well-impregnated wooden sleepers fixed firmly to the foundations on metal sleepers, on blocks and sleepers of reinforced concrete in order to discover whether these arrangements diminish corrugation. The rails should be solidly attached to their supports, so as to damp out as much as possible any vibrations to which they are submitted.

It is not convenient at the present time to go further into the question of causes and remedies, for the Association Allemande de Tramways et de Chemins de Fer d'Intérêt Local has recently appointed a commission to carry out, in conjunction with Dr. Puppe, detailed investigations into the nature of rail metal and other causes of corrugation.

THE PRICE OF ELECTRICITY.*

BY EDW. W. COWAN.

(*Concluded from page 897.*)

Summary.—The author criticises the principles on which the charges for electrical energy are usually based, this basis being an equal rate of profit from every class of consumer. Although this principle is safe, the author argues that best economic results cannot be obtained because the factor of demand is entirely ignored. The demand for electricity is of a "composite" kind, energy being required for light, power and heat. Classified tariffs should be adopted so as to secure the greatest economic advantage. The author supports his views by reference to the adjustment of prices in railway freight charges and other lines of business.

In diagram No. 2 I have attempted to isolate and depict the characteristic features of the principle I am endeavouring to establish.

This diagram requires some explanation. In the first place, it should be pointed out that the curves representing the respective elasticities of demand for the three commodities, light, power and heat are not based upon any observed results, nor has any attempt been made to estimate their character in this respect. They are deliberately drawn to fit in with my argument. Important factors have been ignored, such as the effect of the load-factors of the different classes of supply and the effect of the diversity in incidence of the maximum demands of each class. In fact, a number of factors have been omitted in order to simplify the diagram, and, not only emphasise, but exaggerate the effects of the use of a "classified tariff." The ordinates represent price, the abscissæ quantity demanded. Three curves, representing the arbitrarily assumed elasticities of demand for electricity for light, heat and power at different prices, have been drawn.

Another curve (dotted black) represents the aggregate of these demands at different prices. This curve has been drawn for equal price for all classes of demand, that is, for equal profit or loss on the supply for each class of consumer.

The curve drawn chain dotted represents cost (including connection charges) plus a percentage of profit. At the point A, where this curve crosses the curve of aggregate demand, the aggregate demand at equal profit of all classes of consumers is found. In the diagram it is seen to be 2·7, the average price per unit of supply being 2.

The other points, C and D, respectively, represent the increase upon the demand which is obtainable (under the conditions shown in this diagram) if the different classes of demand are differently priced.

At A all classes are charged 2 per unit of supply.

At C the light consumers pay 2·5 per unit, the power consumers 0·9, and the heat consumers 0·8. The aggregate demand is increased under this differentiation to 4·0 and the mean price reduced to 1·49. This increased demand has been obtained without charging the light consumers a higher price than the price at which they could supply themselves collectively. Inspection of the diagram shows that they could not supply themselves at a lower price than 3·25 and clear their expenses of production. Therefore, light consumers are not being penalised and the power and heat consumers are not being subsidised at their expense.

At D the light consumers are charged 2, the power consumers 0·8, and the heat consumers 0·6, the average price per unit being 1·13. Here the light consumers obtain no benefit from the "classified tariff" compared with the "equal profit," but they are not penalised. A comparison of the results shows that at D, under the "classified tariffs," more than twice the demand is obtained, and at a lower price, viz., 1·13 per unit, as against 2 under the "equal profit" tariff, which lower price represents an advantage to the power and heat consumers, while the light consumers neither gain nor lose.

The power and the heat consumers both gain the advantage of obtaining a supply which would otherwise have been beyond their reach. In short, the benefits of electricity supply are extended to a larger area. From a subjective standpoint the light and power and heat consumers all stand in the same position. The "classified tariff" constitutes under the assumed conditions, subjectively speaking, an "equitable tariff."

It may be pointed out that the conditions of supply are often such that only a very small increase in capital expenditure is necessary for largely increasing the output. Mr. Arthur Wright, referring to Marylebone, said, in 1908, that they could double their output by an increase of 8 per cent. on their capital outlay, and if they could double their output, the average cost of their supply would be reduced from 4½d. to 2½d. per unit, a drop in price of 44 per cent. In the diagram doubling the output from 3 to 6 is made to show a reduction of cost of production per unit of about 37 per cent.

It will be noted that care must be exercised in determining the tariff, as, if the price is fixed too low for any one service, the demand at that price may exceed expectation and lower the mean price below mean cost. It is not likely that the course of demand can be

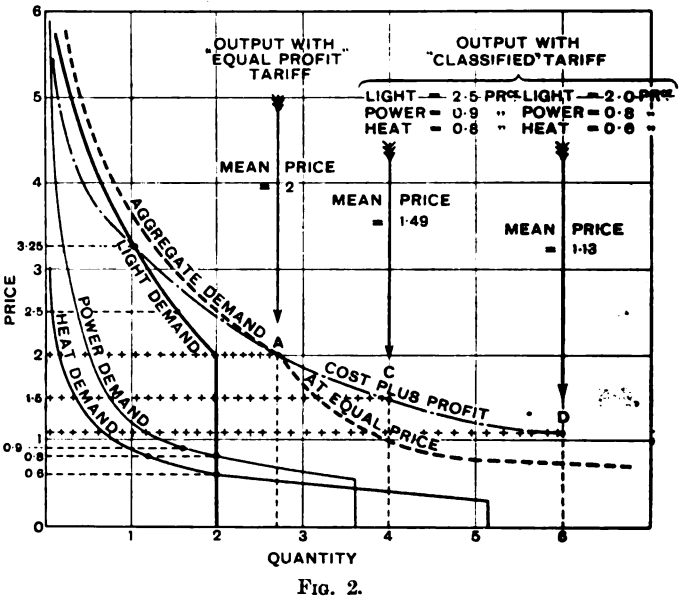

FIG. 2.

predicted with exactness, and consequently provision must be made for error of judgment. This can be done either by not attempting to obtain the maximum possible output or by adjusting prices for a rather larger profit than the normal and setting aside a reserve fund which will be available for making good any deficiency due to error, until correction can be made by price adjustment. The adjustment would generally take the form of deferring a reduction in price which would otherwise have been made.

The circumstances in every case will differ, and the diagram shown, depicting hypothetical conditions, only indicates the character of the problem and exhibits the possible effects of ignoring the factor of demand. In practice, the elasticity of demand can only be estimated, but a study of the market price of competing supplies and of the intrinsic advantages of electricity as a medium for the supply of light or power or heat, make it possible to arrive at useful approximations.

I think that engineers instinctively feel that they have a public duty to perform in protecting their industry from what they believe to be a vicious practice, viz., that of selling any commodity at a price below its cost. They feel that deliberately selling upon such terms tends to break the market price, and that it is therefore an illegitimate and injurious practice. They hold that for the sake of any temporary or individual advantage the gains would be ill-earned if the means adopted dislocated the machinery of the market. With this view we can be entirely in agreement. But is there really any element of unfair competition or any breaking of the market price in the adoption of a system of "classified tariffs".

Is any injury done to the theatrical business by charging for the seats in theatres in accordance with this system, that is, in adapting the prices according to demand for each class of seat without regard to making an equal profit from each class? (Diagram No. 2 is also applicable, *mutatis mutandis*, to a theatre economy.) Clearly both the theatrical proprietors and the public would suffer loss if the seats were sold at prices which contributed equal profits from every part of the house? It is the integrated cost which should be referred to the integrated demand and the integrated price adjusted to secure an equation. Such a process secures the emergence of the largest gain. On the other hand, the selling of any commodity strictly upon the basis of equal profit is, I submit, likely to be not only uneconomical but commercially injurious in many cases. The following diagram (No. 3) statically indicates the forces which, according to this conception, are at work.

As there cannot be two prices in one market, it follows that all the contributors producing at a relative advantage will make relatively larger profits, which are called "producers' rents" in the diagram. If the producers who contribute the portion OD_2 sell their product at the arbitrarily chosen price D_2D_1 without regard to the market price QQ_1, what will become of the surplus represented by the area CBD_1D? If the producers surrender this surplus will the consumers gain it? Clearly not, because the market machinery will not work with different prices for the same commodity. The surplus will be secured by middle men, possibly landlords, whose business it will be to equalise the market price and pocket the differences thus yielded by the producers. It will be admitted that if "rents" are unavoidable, they should accrue to the producers rather than to a class of interceptors who render no essentially useful service. Competition among producers will keep

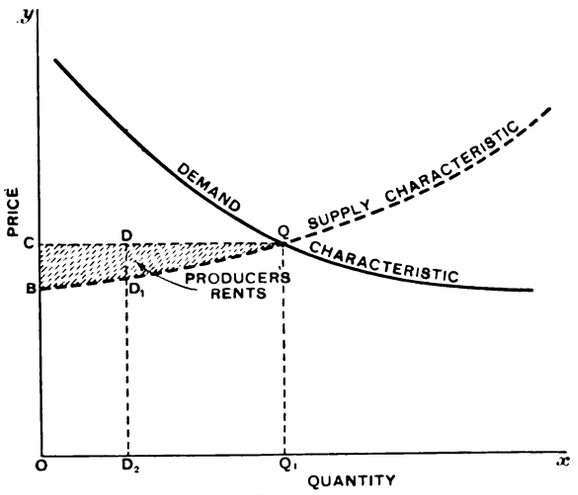

FIG. 3.

these rents pruned down to a minimum. We may or may not approve of the existing commercial system, but isolated attempts to amend it in accordance with abstract ideals are not unlikely to be mischievous in their effects.

Turning, now, to the practical import of the criticism of this Paper, what does it amount to? There exists a great potential demand for electricity for power and heat uses. This potential demand awaits the sufficient lowering of prices to render it active demand to the great advantage of the community from many points of view which affect its well-being. Some years ago I estimated that electricity at three units for a penny would compare favourably in the provision of useful heat, with coal burnt in open hearths at from 15s. to £1 a ton. The hygienic advantage and convenience of electric heating and cooking are generally realised, as also is the convenience of electric refrigeration. Rapid strides have been made in recent years in the direction of economy of production, and the effective demand for electricity for power use is already large and is daily increasing. Further progress in this direction may be expected, but the distribution of heat and cold by electrical means has scarcely commenced.

The undertaker, realising that the great potential demand cannot be rendered active for many years to come, if it is to await the results of progress in the development of economical method in the generating and distribution of electricity has endeavoured to reach it by means of various commercial expedients. The position to him is in some ways tantalising. Over 80 per cent. of the producing power of our electricity supply works lies inert owing to the irregularity of the incidence of demand, the use of storage batteries only being commercially possible to a limited extent in levelling the fluctuations in the "demand" characteristic. He sees all this producing plant lying idle and he knows that, though the storage of electricity may be commercially impossible, the storage of heat and of cold is comparatively cheap and efficient. There are therefore before him the three necessary factors:

1. A great demand
2. Idle producing power.
3. Means of storage of the objective of a great part of that demand, viz., heat and cold.

No wonder, then, that he asks himself—can no alchemy be found which may bring these factors into effective combination?

But at the outset of his inquiry he is faced with the difficulty that one possible means of operation is taken out of his hands. He may not adapt his supply to demand by any classification of his charges. The industry has established the principle that such a course involves inequitable treatment of the consumers and is therefore inadmissible. While admitting that perhaps the system of "equal profit" may have provided a good working hypothesis during the early stages of the development of a new industry, I do earnestly desire to see engineers emancipated from this restriction at the present time. I do not wish to exaggerate the importance of the views I hold, but I trust that it will be realised that there is a specific gain in the system of classification. Without saying that the adoption of the "equal profit" system has been a mistake in the past, I hold that accepting it as being a system essentially right in principle is due to a faulty conception of the complex of electricity supply, regarded as an organic whole.

The keystone of my position is this: that a system of graded prices can secure finer adaptation of supply to demand. I hold that the law of supply and demand is a natural law, and as such, may not be disregarded.

The objective of the law of supply and demand is the achievement of their closest incidence. It is this end which should be kept in view, viz., the attainment of the largest demand of the most profitable kind which pays the expense of production plus a reasonable margin of profit. With one exception, it does not matter in the least, from any other point of view worth taking into account, what is the relation between the cost and the sale of the various portions of supply which make up the whole. That one exception is that no class of consumer should be charged a price in excess of that at which it could supply itself. (A corollary follows from this principle, viz., that two classes may not be charged prices, the sum of which is in excess of that at which they could supply themselves in combination.) Adherence to this principle is essential from a juristic point of view. Any infringement of it constitutes an infringement of a prescriptive social right.

I plead for a due regard of two factors (1) the "character of demand," and (2) the "intensity of demand." Attempts are now made to allow for the influence of the former factor in adjustment of price in relation to diversity of maximum demands, &c., but the latter factor is entirely disregarded in pricing electricity supply. Though I have made little reference to it, I do not overlook the importance of the "encouragement" factor. It is right and proper to attract relatively profitable business, because it is in the common interest that this should be done.

It is the largest and best class of demand in respect to time, the achievement of which should be sought. I do not understand the oft repeated argument that supplying low-priced units displaces the supply of high-priced. There is no limit to supply other than the limits of demand, and it will pay to cater for all demand which can be supplied within the limits of the mean cost of production.

Inert plant is a bad thing, but is not inert power to supply a want an equally bad thing? The neglect to supply any possible demand is an abuse of the power of monopoly.

It is in the hope of giving some assistance towards the removing of an obstacle to the advance of the use of electricity that this Paper has been written. The practical effect of the removal of this obstacle may be large or it may be small, but economists are familiar with the fact that small price changes sometimes alter the channels of great volumes of trade. We cannot afford to disregard any principle, however small its dimensions may be, which is a principle of essential economy.

My thanks are due to Mr. William Schooling and to Mr. Mark Barr for useful criticisms and suggestions, and also to Mr. Sydney Morse, who has been good enough to express the opinion that "classified" tariffs are not illegal.

In an appendix the author reproduces the clauses in the Electric Lighting Acts referring particularly to prices charged, and then passes on to the Railway and Canal Traffic Act.

Railway and Canal Traffic Act, 1888. 51 and 52 Vict.

Definitions. Clause 55. "The term 'undue preference' includes an undue preference or unreasonable prejudice or disadvantage, in any

Digitized by Google

respect, in favour of or against any person or particular class of persons or any particular description of traffic."

Ditto, *Clause* 2.

"In deciding whether a lower charge or difference in treatment does or does not amount to an undue preference, the Court having jurisdiction in the matter, or the Commissioners, as the case may be, may, so far as they think reasonable, in addition to any other considerations affecting the case, take into consideration whether such lower charge or difference in treatment is necessary for the purpose of securing in the interests of the public the traffic in respect of which it is made, and whether the inequality cannot be removed without unduly reducing the rates charged to the complainant."

The consideration of the legality of "classified tariffs" is a relatively unimportant one, because if such tariffs were found to be illegal, though advantageous to the community, the law could and would be altered in due course.

It does not appear to me, however, that "classified tariffs" are illegal, though the approval of the Board of Trade would be required. The term "undue preference" in the Electric Lighting Act, 1882, was translated from the Railway Acts, and the assumption is that it would bear the same meaning and significance in both cases.

We find that, in regard to railway rates, the system of classification is adopted and authorised in the face of the illegality of "undue preference." The conclusion appears to be that the preference given to some classes in the classification of rates is not an "undue" preference. And it seems to be a fair inference that if such preference is not "undue" in the case of railway rates, it would not be held to be so in the case of electricity supply rates.

Some light is thrown upon the question by reference to the treatment of the difficulty in America. There, after considerable controversy, the principle of "discrimination" (or classification) has been generally adopted, and H. R. Meyer in his work on "The Government Regulation of Railway Rates," says: "The effect of that discrimination was a heterogeneous mass of railway rates that knit the different producing, distributing and consuming sections of this country into a more compact trading unit than was to be found anywhere else in the world and carried the exploitation of our resources farther than has been carried the exploitation of the resources of any other country."

The above quotation shows that in America the beneficial character of discrimination or classification has been recognised. But the dangers of an abuse of the system were also recognised, A clause in an American "Act to Regulate Commerce" provides that discrimination must not be "undue or unreasonable."

On the Continent there has been considerable controversy on the same point and in the earlier days, before the essential economy of classification was recognised in connection with railway working, a system, of charging for rail transport was adopted which was practically identical with the "Hopkinson" method in the case of electricity supply. In the Alsace and Lorraine State Railways a fixed charge for terminal expenses was made, and thereafter an equal charge per ton-mile on all goods. The arguments which led to the adoption of this system were identical with those which have led to the adoption of similar systems in the electrical industry in this country. The method was abandoned when the benefits of classification were realised. The new tariff was called a "compromise tariff," but it was virtually a "classified" tariff. The above references seem to show that classification is regarded as being legal notwithstanding the illegality of "undue preference," and it seems to me that the Board of Trade would not withhold their consent to a system which was identical in principle with a system which has been accepted as being legal and beneficial in the case of railway working and which has been adopted in the face of the enactment that "undue preference" must not be given to any consumer.

We give below an abstract of Mr. S. L. Pearce's remarks in connection with Mr. Cowan's Paper, as these are of much interest and could only be referred to briefly in the B.A. diary last week.

Mr. S. L. Pearce (City Electrical Engineer, Manchester), after some appreciative remarks upon the value of the Paper as a contribution to the literature of the subject, said that he was considerably in accord with the abstract principles set forth, and he thought also there would be a considerable measure of agreement amongst engineers with the main argument of the Paper. The great difficulty lay, however, in the application of the principle of "classification" to actual tariffs—that is, in translating an admittedly beneficial principle into an equitable tariff—which could be arrived at on a scientific basis and one that would not be open to constant revision or adjustment. He held that all tariffs should be flexible as far as possible, but at the same time not open to the charge of "undue preference." He had advocated the remission of certain charges on capital in the case of new power consumers for the reason that the cost of modern plant on a kilowatt basis was only one-third that of plant installed, say, eight years ago. This enabled new business to be secured which would otherwise be lost, and at the same time broadened the basis over which all standing charges were spread, and so benefited other classes of consumers through a reduction in their tariffs. The remarks of the author (at the bottom of p. 11 and top of p. 12), in regard to the possibility not only of conferring benefits upon power and heat users, but of supplying light users at a lower price than would be possible if the principle of a uniform rate of profit from each class of consumer were adopted, were borne out by the speaker's actual experience with a large undertaking supplying various classes of demand. He thought the point to be emphasised was not the "equal profit" basis, which was more or less a fallacy, especially on "flat rate" sales, but that there should be a margin of profit on all sales, although the relative profits made on the various classes of supply might and would differ widely. Within the limits of this principle he thought there was considerable room for "classification." The introduction of the metal filament lamp had, he thought, impressed engineers more than anything else that they were selling light and not electricity, and he was in accord with the author in considering that the supply of electricity might fairly be considered as being "of a joint character." Mr. Cowan had pleaded for more consideration to be given to two factors, viz., "the character of the demand" and "the intensity of the demand." With regard to the former he (the speaker) thought that taking fully into consideration the effect of "diversity factors" met the first point. He would like to ask Mr. Cowan to explain more definitely and fully the exact meaning, however, of the expression "intensity of demand." The actual true cost to the undertaking of supplying some particular consumers was practically unascertainable, and he thought Mr. Cowan's explanation of the example given, in which a profit was apparently made by selling at a loss, was explained on this hypothesis. As far as municipal undertakings were concerned, he felt sure that most engineers would agree that the rendering of the largest service to the community generally, compatible with financial stability, was of greater importance than financial stability plus large profits.

THE RELATIONS OF SCIENCE TO INDUSTRY AND COMMERCE.*

BY R. BLAIR.

Summary.—The author in dealing with this subject gives an abstract of the views of students, university teachers, manufacturers and consuls on the present connection between science and industry. It is shown that, while matters are improving, higher education is of too theoretical and detached a nature to make its recipient immediately useful in the commercial world. Remedies to counteract this state of things are suggested.

In this Paper attention is restricted chiefly to the relation which exists between the scientific and technical education, provided at the higher institutions in this country, and the after careers of the students. The views of 150 students of university rank have been selected, while 500 letters of inquiry were addressed to teachers of repute at home, in France, Germany and America. Inquiries have also been made of manufacturers and British consuls.

First, as to the views of the 150 students. These students all belong to the class for whom the earning of a living is imperative, and in the main they represent Oxford, Cambridge and the London institutions of university rank. Among minor points made by them are these: The engineers emphasise the need of workshop practice under commercial conditions, finding that their future is in danger of being marred by lack of "works" experience, and some of those who have become industrial chemists express the need for a five years' training, three for the degree and two for research. The students also complain that posts are obtained not on merit, but through influence. This contention is pointedly illustrated by a university college professor, who states that he knows one man who holds a most important berth, and is undoubtedly a first-class man in every sense of the word. This man took his university training as a mechanical engineer and graduated with first-class honours, after having had "works" training extending over some eight years. On leaving college the man approached every mechanical firm of importance in Scotland in the hopes of getting a start. He found it impossible to do so. Finally, *through influence*, he did manage to obtain a junior berth, and is now the head of an important concern.

The most striking feature of the present occupations of the students is that only 10 per cent. have found their way into industry and commerce; another 10 per cent. have entered the higher ranks of the civil service, including technical posts. Some half-dozen are in the church; another half-dozen are practising medicine; the remainder have taken to teaching, and it was clear in a fair number of instances that selection of a profession was not a matter of choice, but one of necessity. Many a man towards the end of his university career discovers for the first time that he has nothing to offer in the industrial or commercial market in return for a salary. If he has no technical knowledge or skill he is, so far as his education helps him, in the same position as a secondary schoolboy, even if he is not handicapped on account of his greater age. Of those, also, who possess technical knowledge or skill, such as students of engineering or chemistry, a good many find themselves offered terms which pride or poverty, or both, forbid them to accept. Sometimes the shop, factory, or business house offers nothing, and occasionally a premium is required. It will easily be understood that under such circumstances an appeal is made by the students for more help in finding

* Abstract of a Paper read before Section D of the British Association.

Digitized by Google

posts for university honours men, who are not eligible for the civil service and who do not care to turn schoolmasters; and it will not be difficult to appreciate that at the critical point in his career (the selection of a means of earning a livelihood) a man is apt to write harshly of the slackness of university life and to complain, as one of the most successful of them has done, that he wanted to be made a chemist, but his university insisted on his wasting his time on divinity, and did not even ask for German.

A great change in the relations of the university and the market has occurred during the last quarter of a century. The general advance in the standard of education has produced a larger sympathy on the part of the market for educational institutions and their products; and the movement in favour of technical education has widened the range of objects of university education, and has perhaps compelled the universities to have regard to the diversities of the world's work, and to the function they should discharge in preparing their students to live. During the period referred to, a large number of technical institutions have sprung up all over the United Kingdom, and within quite recent years there have been strong influences at work to bring about co-ordination, if not incorporation, of the greatest of the technical institutions with the universities within whose areas they have emerged. The danger in this process of amalgamation is that it may be premature. It may come about before the realisation of what each institution in its own way, and in its own time, has had to contribute to national problems, and before it has been fully recognised that the annexation of a technical school is not merely the end of a rival, but the beginning of a new public responsibility, and with the result that the vitality and, if you like, the harsh industrialism and commercialism of the technical institution may be too much submerged by "academic control."

The evidence placed at my disposal shows, on the whole, a tone of great hopefulness. This hopefulness of tone is common. It is displayed by the newest of the large municipal technical institutions in the heart of a great industrial centre, and by some of our oldest universities. It is becoming evident that the institutions are recognising that, however much the market, in its quest after cheapness, has failed to distinguish the real from the spurious article, the institutions themselves have not been without much blame for placing inefficient machines on the market. An eminent professor of chemistry tells me that his whole "professional life is strewn with examples of the unwillingness of industry and commerce, the State, and municipal authorities of this country to take advantage of the services of young men who have received the highest technical training as chemists." But, he adds, "there is a tolerably rapid improvement taking place," and "we who are urging the importance of employing these highly trained young men have to remember that there has been a great lot of poor stuff turned out from the universities and technical colleges, and that the British manufacturer has a good deal to say in his own defence."

The evidence from the engineering colleges and institutions is, on the whole, satisfactory. Here and there may be found somewhat doleful notes to the effect that the large majority of state and local authorities do not lay themselves out to take advantage of technically trained men, and, in one case, a view that has much popular currency has been put to me in fairly strong terms. It is to the effect that employers, especially those who have not very large and important undertakings, but who, nevertheless, would have their businesses improved by securing technically trained men, have an ignorant prejudice against such assistance. It is suggested as the possible explanation of their attitude that the employers fear that if they engaged men of greater attainments than themselves, they would simply be raising up possible opponents in their own line of business. There may be some truth in this view, which does not, of course, apply to first-class firms, but there is, I think, another view worth consideration: That the size of the business concern (the amount of capital sunk in it) has much to do with the employer's attitude. The employer does not possess the faith that will enable him to risk the addition of another salary to his working expenses; and no one, without a fair trial, is able to give him the mathematical demonstration, which he seeks, that the salary might often be saved merely out of the waste of materials which exists owing to the absence of scientific knowledge on the part of his men, of the materials they are handling, and to their having to feel their way by experiments that are more in the nature of guesses. Such firms will be converted only by the example of others.

There is abundant evidence, however, that there is much less prejudice than formerly, and that there is a growing tendency on the part of State and municipal authorities to secure for their services engineers who have received the highest training, and that this attitude is especially true of certain industries whose success depends absolutely upon highly competent trained scientific experts, as, for example, the steel industry. I suggest that the growth of this attitude corresponds generally in time with increased recognition on the part of the teaching institutions that engineers cannot be wholly made at college. The colleges have at length realised that the student must from the first learn the limitations of practical engineering, and that this can only be done by the introduction of a practical atmosphere and without sacrificing any of the physical principles of engineering already well taught at the colleges. One of our ancient universities says: "We have not now much reason to be dissatisfied with the attitude of employers towards our (engineering) students." Several of the largest of the technical institutions say they have no difficulty in placing their best students, and one university college states that there is a standing demand, as soon as the college year ends, from several of the heads of engineering establishments within the neighbourhood of the college for the best students. But these heads of firms demand the "best," and are willing to pay a living wage right off to youths who have never before been in works, and have only their college training as qualification. It is added that second or third rate men are in very little demand, and there is often a difficulty in not being able to recommend youths of sufficiently high standard to fill the vacant posts. This case recalls other colleges where students (the "best," at all events) have no difficulty in securing places owing to the personal connection established between the heads of the neighbouring works and the head of the engineering department.

It has been pointed out to me both by professors and the heads of large engineering firms that there is still a defect in the college training of young engineers which ought to be immediately remedied. The view is so well presented by one of the colleges that I give it *in extenso*: "There are certain defects in the average college training. I consider that the question of cost in design and the commercial side generally, receive quite inadequate attention in most colleges. Practically all engineering firms exist for making profit. Modern competition makes economic design, good efficiency and cheap upkeep absolutely imperative. The employer wants men who can in their designs give the most for the money. It is, therefore, insufficient to teach design on physical principles alone. Methods of production, ease of repair, depreciation, even conditions of transit in large machines, all these and more must be considered in effective design. Such limitations as these should, I think, be brought before the student in greater measure than they are attempted at present. This will tend to practicalise the student while his mind is still formative.

The case of chemistry is more difficult, since there is no doubt that the British chemical industry has suffered from German competition. Our manufacturers did not for some years understand the use to which the chemist could be put in their works, though it is gratifying to find there is now evidence of change. The tendency has been, especially among municipal authorities, to underpay such technically trained chemists and, as regards private employers, the author is of opinion that British manufacturers as a body are not yet fully sensible of the advantage which they might obtain by the employment of skilled chemists in manufactures in which chemistry plays a prominent part. Foreign chemists resident in this country recognise this, and there is no doubt that they have chosen for their sons a university education as a preliminary to business life.

As regards evidence of change. It appears that many of the largest technical institutions have no difficulty at the present time in placing their trained chemists in good posts. While an analysis of class lists of old chemical students shows that a large percentage is now engaged in industrial work.

Attention should, however, be drawn to the poor class of chemical teaching provided at the universities. Much of it is simply good secondary class work, and does not teach a student to think for himself. When entering a research laboratory after such a course a student is rarely an independent thinker, and has to struggle to develop his resources. Again the business faculties of students at this stage are poor, and they are not qualified to take up responsible positions. After the "research" years this is changed, the student thinks for himself and improves in business style. All this means time, however, and the British parent does not care to afford to keep his sons at the university until they are 24 to 25 years of age, especially as a period of probation has afterwards to be served in works, unless he sees that his money is going to be a good investment.

Industrial and commercial firms almost all express their preference for elementary school boys. A good many speak in high terms of the value of evening schools, while insurance companies especially seek for the secondary school product. There is some call for men trained at the highest institutions, but this call is so much confined to firms whose works or business require technical skill that it is fully evident that the others do not yet feel the need of such men, nor know how to use them.

A fairly common plan of training for those who will rise above the rank of "hands" is the elementary school education, combined with

Digitized by Google

evening classes. There is a demand for the "practical" man, and a view, which is not altogether uncommon, is more sympathetic with higher education is that a man with practical training alone can do much; a man with technical training alone can do little; a combination is, therefore, essential. If only one of these can be had that must be the practical man.

Though in general the value of evening schools is recognised by employers, yet there is a fair amount of criticism; for instance, that they are not practical enough. They think that such schools may help individual pupils, but it does not enter their mind that they may also aid their industries. Evidence goes to show that the direct connection between the universities and industry is small, though many manufacturing and trading concerns recognise the value which a full university education affords in after life. It is felt that the present system of education in these institutions together with the length of the vacations and the great freedom enjoyed by the undergraduate are not altogether suitable preliminaries to a business life.

It, however, appears that many British manufacturers, especially those under younger management are displaying their economic sense in a new and interesting direction. Firms manufacturing common commodities and employing thousands of hands have shown that not only do they employ scientifically trained engineers, but they employ public school men as managers, they employ on their permanent staff doctors and dentists for the sake of their hands, they provide much for the social and economic welfare of their workers and generally show that they take as much interest in the human as in the other material which comes into their works. They find that in the interests of their business the human material, as much as the coal and the steel and the sugar and the flour, can respond with more efficiency to scientific and generally enlightened management.

(*To be continued.*)

ELECTRIC RAILWAY CATENARY TROLLEY CONSTRUCTION.*

BY W. N. SMITH.

Summary.—The author describes recent practice in catenary construction, discussing the various features of the different forms in use. He believes that the roller type of trolley may possibly prove a distinct improvement over the present sliding bow for trunk line work.

During the past 20 years the overhead trolley for electric railways has become such a familiar type of construction, and apparently so settled in practically all its details, that it is apt to be regarded as commonplace compared with many other features of electric railway equipment. As long as electric energy for train propulsion was everywhere standardised at 500 to 600 volts direct current, trolley construction practice followed a practically uniform line; but since 1904 wide departures have been made from the original forms of railway motors, both as to current and voltage. This advance, made entirely in the interest of economy in transmission, has been accompanied by radical changes in trolley construction, which have required the closest engineering attention and have lifted it above the level of the commonplace into which it had generally come to be relegated.

This Paper is intended to be a review of current practice in electric railway catenary construction. As interurban railways grew in importance, and in the size and speed of their equipment, not only did the necessity for economy in power transmission grow increasingly important, but the problem of collecting trolley current at high speed became more and more serious. The figure 8 and grooved types of trolley wire afforded some relief, but as supports were still 100 ft. or more apart the points of suspension caused slight changes in elevation of the wire, sharp enough to make trouble at high speed. It was not until 1904 that a new step was taken, namely, the elimination of the sag by means of more frequent points of support of the wire, resulting in the development of the so-called catenary type of suspension. This has come to be accepted as a practical solution for high-speed trolley operation. The principal features of this construction are the flat and smooth alignment of the trolley wire for high speed, the prevention of a trolley wire falling to the ground when broken (this is imperative at high potentials), and the use of a pneumatically-operated sliding bow for making contact. It has, however, the drawback of responding more sluggishly to unevenness of the trolley wire than the wheel and pole type of trolley, and this has resulted in a number of cases in the retention of the wheel trolley even in 3,300 and 6,600 volt lines. The writer's observation leads him to believe that the objections to the bow trolley have developed particularly where the catenary construction is defective.

Catenary construction is divided into three types as follows:—(1) The plain, single catenary, with the trolley wire hung directly from the messenger wire. (2) The compound or three-wire single catenary, in which the trolley wire is suspended by clips of uniform length from a tight secondary wire just above it, this secondary wire being supported by hanger rods of varying length from slack messenger wire above it. There are several variations of this type and it permits the use of devices which maintain a uniform tension on the trolley wire through any range of temperature. (3) Double catenary construction, consisting of two messenger wires and one trolley, the latter below and between the other two, the three wires being at the corners of an equilateral triangle and rigidly connected by triangular pipe spreaders varying from 6 in. to 6 ft. on a side according to the sag of the messenger wire. The excessive rigidity of this type has been found to be undesirable in practical operation, and it has been successfully modified on the New Haven railroad by stringing a second trolley wire and fastening it a few inches below the first by clips at points halfway between the original trolley wire hangers.

The second of these general types has been extensively developed in Europe, particularly that feature which enables the maintenance of uniform tension on the trolley wire. Conspicuous examples of this type are the single-phase lines of the Blankenese–Altona–Hamburg–Ohlsdorf line in Germany, and the Rotterdam–Haag–Scheveningen line in Holland.

Poles and Bridges.—Where wooden poles are used they should invariably be treated with some preservative, preferably of the creosote type, before being set. Steel poles can be had in three types. The familiar two or three-section tubular pole, in either

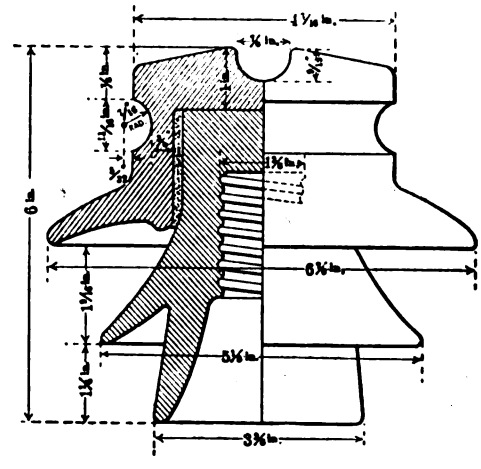

FIG. 1.—PORCELAIN INSULATOR.

standard or extra heavy pipe; the "tripartite" pole, built up of re-rolled Bessemer steel U-sections with malleable iron collars and spreaders; and the "diamond" pole which consists of two sheet steel V-shaped troughs tapered and flanged over the edges, one being driven lengthwise within the other to form, when assembled, a box shaped pole, the extra strength lying in the extra thickness of the overlapping flanges. The relative merits of these three types of steel poles may be briefly summed up by saying that the tubular type is the least economical of weight for a given strength, and that while the diamond pole is superior to the tripartite in the matter of weight economy, the tripartite has a great advantage in that the Bessemer steel composing it is almost rust-proof and that every inch of metal surface upon it can be reached with a paint brush. Its taper can also be varied to suit local conditions.

Reinforced concrete poles have come into use during the past few years for railway trolley construction. Under favourable conditions they can compete with cedar or chestnut poles as to first cost; they are, roughly speaking, about twice as stiff as a cedar pole and of 30 per cent. to 50 per cent. greater ultimate strength. Most important of all, they are practically indestructible. A considerable number of them are in use on the lines of the Fort Wayne & Wabash Valley Traction Co.

On account of the load being from two to three times that carried on a single bracket pole in standard direct suspension, it is necessary to use heavier poles for catenary work. If of wood, they should average 25 in. in circumference at the top, and should invariably be seasoned and treated with creosote, at least, at the butts. The standard setting should be 6 ft. for a 30 ft. pole and 6½ ft. for a 35 ft. pole where the wire is at a high elevation. Over highways,

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

19 ft. is usually high enough, but in the steam railroad electrification carried out in this country the standard height of trolley wire, except under low bridges, is 22 ft. above the rail. Bracket poles should be set with 14 in. or 15 in. rake, as they will pull up to about 1 ft. rake after the load has been applied. On steam railroads particular care must be paid to side clearances. 8 ft. from centre of track to the face of the pole is a minimum, and some roads require more. With an 8 ft. clearance, a bracket 10 ft. in length is sufficient. On curves, brackets must be so inclined from the horizontal as to be nearly parallel to the position taken by the pantagraph bow, the outer end of which will tilt up considerably, due to the elevation of the outer rail. For attaching bracket truss rods to pole tops, the three-part pole-collar is preferable to any other means, as a single-pattern forging is sufficient not only for the truss rod but for constraining the body of the bracket. Insulator pins should be tightly adjustable on the brackets and should be made with a two-part clamp base, which the writer believes preferable to one with a J-bolt base.

Porcelain insulators of the petticoat type, are now universally used, and even over steam railroad tracks they have given no special trouble from gathering soot. The types used on the Erie and the Denver and Interurban lines have been uniformly successful, for three years on the former and two years on the latter railroad. The general form of this insulator is shown in Fig. 1.

Brackets ought also to be stronger than are usually made in direct suspension, particularly if over steam railroads. In the equipment

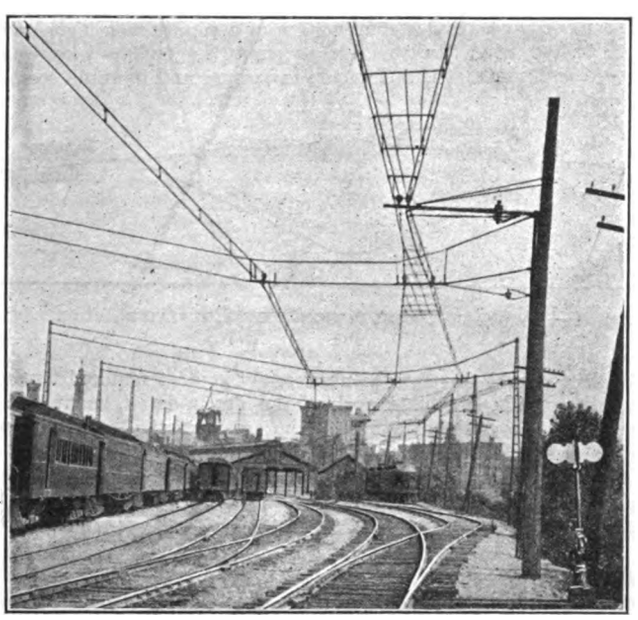

FIG. 2.—OVERHEAD CONSTRUCTION AT ROCHESTER TERMINAL OF THE ERIE RAILROAD.

designed by the writer for catenary construction on the Erie Railroad, two truss rods were used per bracket. Some forms of bracket are made with two horizontal members, one on each side of the pole. To guard against accidents and minimise breakage in case of accident, the writer believes that it is desirable to design the pole attachments to the bracket, so that if the trolley and messenger wire break, the bracket and truss rods may be swung around the pole as on a hinge, rather than be broken off or twisted out of shape. This is effected by using pole collars at the butt of the bracket and at the point of attachment of the truss rod, which have the additional advantage of obviating the boring of holes through the pole.

Catenary Spans and Bridges.—The expense of steel bridges for supporting catenary trolley wires over more than two or three adjacent tracks can be greatly reduced by using span wire construction. A number of spans constructed under the writer's supervision at the Rochester terminal of the Erie railroad are illustrated herewith in Fig. 2. In this design the span wires and all supporting fittings are earthed. The trolley wire is supported by suspending from the span wire a stirrup of the same size of tee iron as is used for the bracket. The same type of pin as well as insulator is used for the span as for the bracket construction on the remainder of the line. The voltage on this installation is 11,000. For lower voltages heavy wooden strain insulators are sometimes cut into the spans without any insulation between the span and the messenger wire at the point of attachment, but the advantage of entirely earthed span wires should commend itself so naturally that it does not seem worth while to go to the extra trouble of working various styles of insulators into them. This form of span is practically in duplicate, though it is intended that the upper should carry the load and the lower act to steady the stirrup sideways. It is hardly necessary to add that steel poles are necessary for catenary span construction of this character, unless there is ample room substantially to guy wooden poles. For this purpose the tripartite pole has been found very satisfactory. The illustration shows seven tracks spanned, being a distance of 96½ ft. across the tracks between poles, and four tracks of the seven electrified.

Some of the latest catenary construction for double track has been supported by a light bridge construction, the most recent example being that of the Rochester, Syracuse & Eastern Railway, recently completed, and illustrated in Fig. 3. This is for 600 volt direct-current construction with bridges 300 ft. apart. It is of the plain single catenary type, without any special adjustment or tension devices. The sag of the cables in a 300 ft. span is about 62 in., the maximum length of hanger being about 67½ in. and the minimum 5¼ in. in length. The form of bridge and foundation is stable and permanent. The side frames of the bridge are 28 ft. between the centres and the spread of each base is 4 ft. The insulators on top of these bridges are of porcelain moulded in a special saddle shape and set on treated timber. There is said to be comparatively little side swaying between bridges. On this particular line the messenger cables are of copper, constituting the feeders and are of 500,000 cir. mils. The feeder was necessary for power distribution

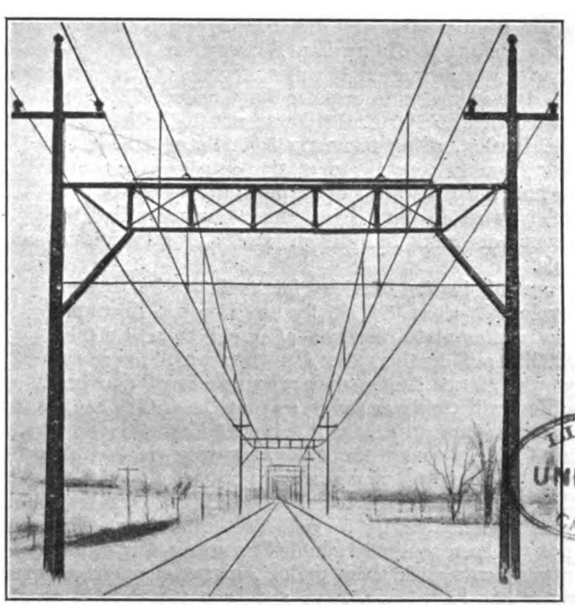

FIG. 3.—LIGHT BRIDGE CONSTRUCTION ON ROCHESTER, SYRACUSE & EASTERN RAILWAY.

and the cost of the steel messenger wire was saved by this combination.

Some figures were recently published showing the relative cost of this type of construction compared with the ordinary wooden pole and span wire construction for double track. The fact that the messenger wires were eliminated and the feeders made to do double duty enabled quite a saving to be made, and the cost of the supporting structures, exclusive of copper conductors, is reported for this particular line as being only £20 per mile of double track more than with wooden pole construction. It is hardly necessary to comment on the greater permanency of steel construction.

Messenger and Trolley Wires.—By reason of their somewhat intimate relationship, it is desirable to consider messenger and trolley wires together. The original and simplest form of catenary construction utilised a galvanised seven-strand steel cable of high strength steel, with hard-drawn grooved copper trolley wire. The messenger wire has varying sags, but a common sag was 10 in. to 12 in. for a 120 ft. span. The trolley wire, which is generally of 3/0 or 4/0 B. & S. gauge, is meant to be perfectly level at average temperature, but owing to the different coefficients of expansion of steel and copper, the trolley wire is relatively tighter at low and slacker at high temperatures than the messenger wire. With the plain type of catenary construction where no take-up devices are employed, the result is that in warm weather the 10 ft. sections between hanger points become slack enough to cause the sliding bows to pound kinks into the wires at the hanger points, and, at

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

Digitized by Google

any considerable speed, mechanically pounding and electrical flashing are both injurious. The only remedy for this situation aside from providing over-lapping breaks, is to pull the wire sufficiently tight so that its strain at maximum temperature will not be less for a 4/0 wire, than 2,000 lb. If the minimum tension at 100°F. is to be 2,000 lb., at 0°F. it will run up to about 5,000 lb., and the elastic limit of the wire is reached at 5,817 lb. As 5,000 lb. is so close to the elastic limit it is to be expected that copper trolley wire pulled tight enough to be effective at maximum temperatures will be likely to get pulled beyond the elastic limit in the course of a season or two, particularly after the outer skin is somewhat worn down by the passage of the moving contact. These considerations may explain much of the trouble that has been experienced with plain catenary construction using hard-drawn copper trolley wire. It sometimes happens that when a road is quite crooked, the elasticity of the poles will do something towards maintaining the tension of the trolley wire at varying temperatures by giving sideways at the curves, but usually the only remedy is to pull out the slack as often as required. This warm-weather slackness can be obviated where a wire can be pulled sufficiently tight to be at a miniumm of 2,000 lb. at a high temperature and 5,000 lb. at low temperature. This can be done with "phono-electric," with steel wire, or copper-clad steel wire. The principal objection to the use of wire other than copper is the decreased conductivity. Phono-electric wire costs more than copper, while steel wire, of course, costs very much less. Both of these wires are so much stiffer than hard-drawn copper that there is a marked tendency to resist kinking. At 11,000 volts the conductivity does not greatly matter when dealing with the usual interurban train weights and distances of transmission.

On the Denver & Interurban Railway, in 1908, phono-electric trolley wire was strung on 45 miles of plain catenary construction, using a dynamometer to register the tension, which was so adjusted that at 100°F. there was not to be less than 2,000 lb. tension, rising to nearly 5,000 lb. at 0°F. This road has been in constant operation for two years and it has not been necessary to pull any slack out of the trolley wire in that time, thus demonstrating the correctness of both the design and the selection of materials.

The use of tension devices for trolley wire as thus far developed, which is chiefly in Europe, does not seem to contemplate tensions of more than 1,000 lb. to 1,500 lb., and furthermore the clips which hang the trolley wire from the secondary wire directly over it are of a type that will yield vertically, so that the trolley can, as it were, carry a wave along with it as it travels underneath the wire. It is the writer's belief that without the upwardly yielding hangers, it is necessary to maintain a minimum tension of at least 2,000 lb.; and that the only excuse for maintaining a lower tension is the ability of the trolley wire to yield at the hangers. Such hangers have not yet been generally adopted for use in this country and the only experiments with them under American conditions of which the writer has knowledge, have not been particularly conclusive. On the New Haven road good results have been effected by a maximum tension of about 5,000 lb. on the trolley wire, and without the use of automatic devices for producing uniform tension under all temperatures.

An excellent feature of the modified type of compound catenary construction used by the New Haven R.R. is the upward yielding made possible by suspending the contact wire from the old trolley wire at points half-way between the original hanger points. There is thus available a limited amount of upward yielding, depending somewhat on the temperature. The clips by which the working conductor is attached to the lower or secondary messenger are fast to both the wires and allow no vertical play other than that due to the yielding of the secondary wire. The European compound catenary, however, has these hanger clips so designed as to permit the trolley wire to yield vertically, and as all new European work seems to be designed along these lines the principle under European conditions seems to be successful.

The other principal feature of the compound catenary is the tension device placed at intervals to take up the expansion in the trolley wire due to temperature. This consists of a system of weights operating by chains over pulleys, pulling against the free end of the trolley wire at the end of each section, the consecutive sections overlapping so that the contact bow slides readily to one before leaving the other, there being, however, no electrical connection between the trolley wires of the overlapping sections except during the passage of the bow. These sections are from 3,000 ft. to 4,000 ft. long and the arrangement serves naturally as a section insulator around which a jumper can be placed if desired. On the line at Rotterdam the builders have cut the messenger wire at every bracket, inserting a strain insulator resting upon the bracket and composed of three insulators so that there are ordinarily two in series. Previous practice adhered to the continuous messenger, but presumably the change was made in the interest of diminishing the effect of changes in temperature of the continuous messenger.

The latest improvement introduced in Europe for eliminating unevenness of operation due to temperature changes is a new design in which there is included an equaliser wire, so-called, which runs above the catenary between brackets without any intermediate hangers, as shown in Fig. 4. Being somewhat shorter and with less slack than the messenger wire proper it tends to lift the catenary at points where it is anchored thereto a short distance away from the brackets, and thereby raises a short bight in the catenary directly under the bracket where the trolley is attached to it, thus lifting the trolley wire at the bracket when temperature is lowered, which would not be the case in the ordinary type of plain catenary construction. In this type of catenary the trolley wire is of hard-drawn copper, while the catenary and the equaliser are of silicon bronze, so that all three have similar coefficients of expansion. In several instances a copper messenger wire has been used instead of steel, this having been done on lines where low-tension direct current was used, requiring feeder copper. It has the advantage of saving the cost of a steel messenger. The fact that both the trolley and messenger are of the same material will greatly lessen the troubles that have been experienced with a steel messenger and a copper trolley wire.

The excellent service being rendered by steel trolley wire on the New Haven R.R. has suggested to the writer that it might be worth while to propose using a combination of a copper messenger and a steel trolley wire. In this arrangement the trolley wire would expand and contract less than the messenger and it would seem as

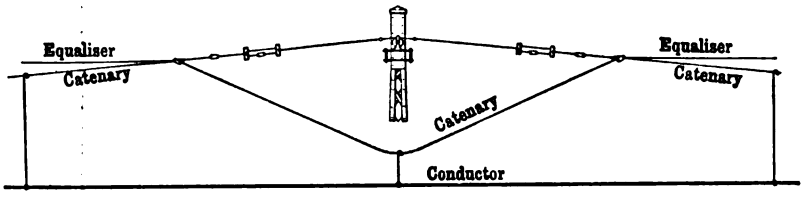

FIG. 4.—CATENARY CONSTRUCTION WITH EQUALISER WIRE.

though it should therefore be more easily kept at required tension. There has not been time to work up the idea in detail, but it is submitted for the criticism of those who are interested. It will probably be more suitable for the higher than lower voltages, but as it is no more difficult to insulate catenary trolley construction for 11,000 volts than for 2,200 volts, the extra cost of insulation due to carrying the higher voltage is insignificant.

(To be concluded.)

TESTING OF HEAT-INSULATING MATERIALS.*

BY F. BACON, M.A.

Summary.—The author describes apparatus he has prepared for calculating the loss of heat in heat-insulating materials. Particulars of tests on a number of materials are given, and also the effect of an air jacket.

The original object of the apparatus here described was to obtain some exact data for calculating the loss of heat through the walls of cold stores in which only a very thin layer of insulation could be allowed, so that surface effects were important, and to provide a conductivity test for heat-insulating material which could be carried out with sufficient ease and rapidity for commercial purposes.

In order to avoid the labour and difficulty of moulding the material to be tested into a shell or covering of complicated shape, recourse was had to the more direct "wall" method, in which the drop of temperature between the two faces of a thin slab transmitting a known heat flux is determined. The inherent sources of error to which such a simple method is liable are: (1) Leakage of the heat flux; (2) incorrect determination of the temperature of the surfaces. It is claimed that both of these errors have been rendered negligible. In fact, the accuracy with which the heat flux and temperature gradient could be determined was greater than could generally be turned to useful account owing to the want of uniformity existing between two specimens of the same material.

* Abstract of a Paper read before Section G of the British Association at Sheffield.

Digitized by Google

Duplicate specimens of the material to be tested are obtained in the form of slabs measuring 18 in. by 18 in. and not more than 1½ in. thick. A thin, flat heating net of uniformly wound resistance wire, interwoven with asbestos, measuring 12 in. by 12 in., is sandwiched in between these slabs, the marginal crack left all round the heating net being filled up with strips of felt. Direct contact between the heating net and slabs of insulating material is avoided by interposing a thin sheet of asbestos millboard on each side. To measure the temperature of the faces of the slabs advantage is taken of the fact that there is no perceptible drop of temperature between a heat-insulator and a good conductor of heat in close contact with it. Sheets of zinc 12 in. by 12 in. are taken, and a flat resistance coil of fine double silk-covered wire wound uniformly over a central 6 in. square of one of their faces. The wire is wound non-inductively and secured to the zinc plates by stitches of thread passing through fine holes drilled in the metal. Zinc plates prepared in this way are inserted on each side of the slabs of insulation, the fine wire coils being in direct contact with the material to be tested. Thin wood covers are now put on both sides, and the whole is clamped firmly together by four bolts, with wing nuts passing through two skeleton frames of wood (Fig. 1). The apparatus is then hung in a vertical plane in a situation screened from draughts and sunlight. The terminals of the heating net are led away through an adjustable resistance and suitable switchgear to a battery of accumulators. A voltmeter and ammeter are connected up to the circuit, from the readings of which the watts dissipated can be obtained. As the arrangement of slabs is identical on both sides of the heating net, the heat generated will divide equally, half escaping through one wall and half through the other. The terminals of the resistances of fine copper wire are connected up to a Wheatstone bridge of the stretched-wire type through a system of plugs, which enables the ratio of resistances of either pair of coils to be determined.

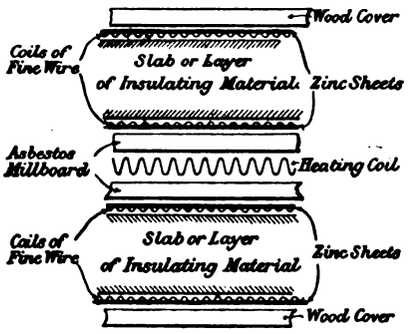

FIG. 1.—DIAGRAMMATIC SECTION FOR CONDUCTIVITY TEST.

By assuming a value for the temperature coefficient of the copper wire, of which the coils are wound, the excess of temperature of the inner over the outer faces of the insulating material can be immediately obtained. The system of plugs also allows of the resistance of any one of the four coils being compared with that of a fifth coil situated in the unheated surrounding air, the temperature of which is measured with an ordinary thermometer. This enables the absolute temperature at the inside or outside of either of the slabs to be determined.

Since the coils which give the temperature of the faces only measure 6 in. by 6 in., while the heating net measures 12 in. by 12 in., it is evident that there is a marginal guard ring of heat flux 3 in. wide all round the central area, through which the heat gradient is determined. As the heating net is wound uniformly, heat is generated uniformly all over its surface; the sheets of zinc, being also the same size as the heating net, help to spread the heat flux uniformly and maintain a direction of flow normal to the surface. With slabs of insulating material not more than 1½ in. thick there can be hardly any doubt that the flux of heat through the central 6 in. square over which the temperature of the faces is determined is uniform, normal to the surface and of density equal to half the watts dissipated in the heating net per unit area. With slabs 1 in. thick it will be seen that, although the total amount of material required for the test is small, the value obtained for the heat conductivity of each slab will really be the average of 36 cubic in. of the material. In all cases the difference of temperature between the faces was measured for each of the slabs, thereby making sure that the heat flow through each slab was approximately equal, and enabling the average coefficient to be determined for a total of 72 cubic in. of material divided between two separate specimens, although the total number of temperature observations involved is only two, and these can be taken immediately one after the other by simply changing over the plug connections to the Wheatstone bridge. When the apparatus is once got together the introduction of fresh specimens is only the work of a few minutes. If it is desired to test some loose material, such as powdered cork or silicate cotton, two similar wood frames are used for retaining it in position.

As soon as the material is in position and the heating coil and fine-wire coils are connected up, a suitable heating current is switched on and the apparatus left until the steady state is attained. The time necessary for this may be anything from 12 hours to two days, depending on the nature of the material and the magnitude of the heating current.

In Fig. 2 are shown the results of a series of tests on boards of yellow pine 1 in. thick. Curve 1 shows the mean difference of temperature between the inside and outside faces of the boards in an enclosed test, as shown in the diagrammatic section, Fig. 1. It will be noticed that the curve 1, in common with all similar curves obtained for other materials tested, is slightly convex to the temperature axis, thereby confirming Nusselt's result that the conductivity of heat insulators increases with rise of temperature. Curve 2 of Fig. 2 shows the difference of temperature between the inside faces of the boards and the external air when the apparatus is arranged so that the outside surfaces of the boards are uncovered; whilst curve 3 has been obtained by plotting the temperature intercepts between curves 1 and 2 for different heat fluxes, and the abscissæ of this curve accordingly represent the drops in temperature which occur at the outer surfaces. The way in which curve 3 bends up shows how very incorrect Newton's law of cooling becomes as soon as the drop in temperature exceeds 40°F. or 50°F. From these curves we can make an attempt to predict the amount of heat that will pass through a partition made of various thicknesses of this material, when certain specified differences of air temperature exist on the two sides. For any definite heat flux, the difference in temperature between the two faces of the partition will be the corresponding abscissa of curve 1 increased or decreased in simple proportion to the thickness; the corresponding abscissa of curve 3 is assumed to be the drop of temperature at the surface that will occur on each side of the partition, and the transfer of heat by air contact will be very sensitive to convection currents. Under conditions of cold-store construction doubtful surface effects on the calculated results have much less relative importance.

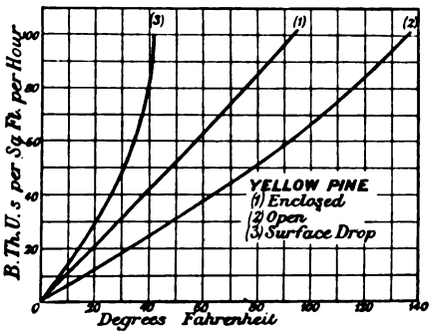

FIG. 2.

The following table shows the specific gravity and coefficient of heat conductivity as determined by the apparatus described for a number of different materials. To facilitate comparison with the results of Nusselt, the conductivities given in the table have been expressed in kilogramme-calories passing per hour through a cross-section of 1 sq. metre when the temperature gradient is 1°C. per metre. To convert the conductivities into B.Th.U. per square foot per hour for a temperature gradient of 1°F. per inch the figures given in the table must be multiplied by 8·05. Thus, for yellow pine, 0·13 × 8·05 = 1·04 nearly, as previously obtained from Fig. 2.

Material.	Spec. grav.	Coeff. of heat conductivity at 50°C. to 75°C.
Yellow pine across grain	0·360	0·13
Teak across grain	0·515	0·23
Expansit Schrot No. I.*	0·051	0·055
„ „ No. II.*	0·049	0·061
Compressed cork slabs	0·166	0·060
Silicate cotton or slag wool	0·330 0·256 0·141 0·113	mean value 0·07
Asbestos sheet, ⅛ in. thick	1·240	0·25
„ millboard, ⅛ in. thick	1·075	0·14 to 0·1
Air jacket in the vertical plane, 1 in. wide, walls of asbestos millboard	—	0·26 to 0·31

The somewhat higher conductivity of Expansit Schrot No. II. compared with No. I. is due to the larger size of the granules composing it.

* A special preparation of cork.

The most efficient grain size is a point of much interest. The heat-insulating effect produced by a porous material is apparently due to the fact that the space which it occupies consists mainly of air split up into such a fine state of subdivision that convection is prevented by viscosity. The more minute the pores the more hampered will be the movement of the entangled air; but a limit will be reached when the pores are made so small that the benefit derived from this cause is counterbalanced by the increased conduction of heat that takes place through the substance of the material itself. From the researches of Clark Maxwell and Winkelmann it appears that the conductivity of perfectly still air is only about 0·02, which may be taken as the ideal towards which the conductivity of actual porus insulating

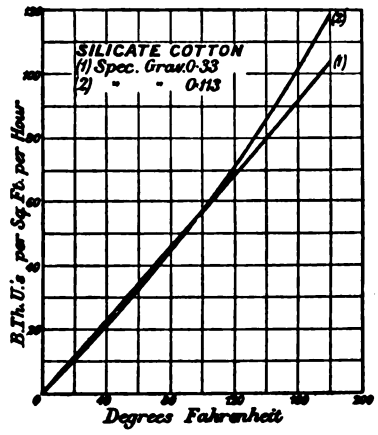

FIG. 3.

material can only approach. The author understands that a conductivity as low as 0·033 has been obtained for Expansit of very fine grain.

Silicate cotton was experimented with in four different densities. Results for the highest and lowest densities, representative of very loose and very firm packing, are shown in Fig. 3. It will be seen that loose packing makes slightly the best insulator for small differences of temperature; but firm packing is much the best when the temperature difference is considerable. On the whole, the results indicate that it is advisable to pack the silicate cotton as firmly as possible, especially as this ensures that the material will not afterwards subside so as to leaves holes which cannot afterwards be filled up.

The apparatus described above for measuring conductivity is also well suited for getting comparative values for heat insulators from the cooling point of view. A steady state is established with some

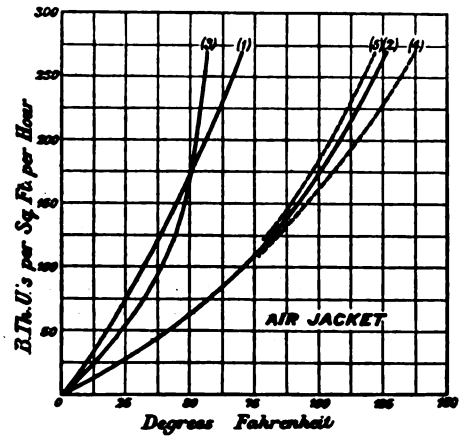

FIG. 4

specified internal temperature, the heating current is then switched off and the rate of fall of internal temperature determined by taking readings periodically.

Results for asbestos lead one to the conclusion that its value as a heat insulator is due rather to its fireproof qualities than to its low conductivity, which, indeed, appears to be no lower than the conductivity of wood. To make experiments on the conductivity of a simple air jacket, two double thicknesses of thin asbestos millboard were inserted in the positions usually occupied by the slabs of insulating material to be tested; curve 1 of Fig. 4 was obtained with this arrangement. Frames were now inserted so that a central air jacket 9 in. by 9 in. was introduced on either side, surrounded by a marginal dead air space about 1½ in. wide. With this arrangement curve 2 was obtained. Curve 3 was constructed by plotting the intercepts between the curves 1 and 2 and must represent very approximately the difference in temperature between opposite walls of the air jackets. It is at once evident that an air jacket of this description is a very poor insulator even for small differences of temperature, and that the conductivity increases enormously as the temperature difference is increased.

Curves 2 and 3 refer to an air jacket with vertical walls. The effect was tried of turning over the apparatus bodily from the vertical to the horizontal plane. The temperature differences for the jacket that was now uppermost rose from curve 2 to curve 4, while for the jacket that was underneath the temperature differences fell from the curve 2 to curve 5. The explanation of these results appears to be that currents of hot air rising freely from the upper horizontal surface of the apparatus enabled the heat to be carried off with only a small difference in temperature between the top of the jacket and the outside air. On the other hand, the hot air produced by the heat conducted through the bottom horizontal surfaces, instead of being displaced by cold air, remained in contact with the lower surface, with the result that the outside wall of the lower jacket rose in temperature, thereby diminishing the difference in temperature between the two walls of the jacket. The heat conductivity of the two jackets can no longer be calculated.

COMMERCIAL WIRELESS TELEGRAPHY IN JAPAN.

THE TEISHINSHO SYSTEM.

BY WICHI TORIKATA.

The investigation of wireless telegraphy in Japan has been continued for about 23 years, the first practical experiment being made by Dr. Rinzaburo Shida in 1886, in an attempt to communicate across the river Sumida. This experiment was carried out by the conduction method, but was not very successful.

After Prof. Hertz announced his epoch making discovery of the electric waves, Dr. Hantaro Nagaoka, Dr. Binnozio Midsuno, and Dr. Osuke Asano were greatly interested by the phenomenon, and the two former especially began their theoretical investigations. Dr. Asano intended to utilise the waves for signalling.

Dr. Osuke Asano is the Director of the Electro-Technical Laboratory of the Imperial Japanese Government, and is also a Professor of the Tokyo Imperial University. His investigation had so far advanced that at the beginning of November, 1897, he was successfully effecting experimental communication over several miles in Shinagawa Bay, near Tokyo. In April, 1900, he had succeeded in practical communication over 34 miles between Otsu and Funahashi. By these practical experiments, he gained much experience and effected improve-

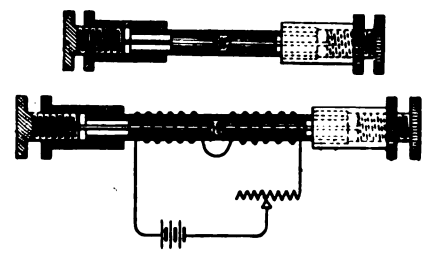

FIG. 1.—TEPPUN DETECTOR. FIGURE FROM THE JAPANESE PATENT SPECIFICATION NO. 11,849 (1907).

ments in his system, and in 1903, he intended to communicate between Formosa and Kyushu. The distance between these islands is 630 miles, and by using 15 kw. he was able to receive some signals at either station, but not yet to effect regular communication. Unfortunately war broke out with Russia before he could establish regular communication between these two islands, and he was obliged to stop his experiment to avoid interference with the wireless operations in our Navy.

During the war, he remained in his laboratory and continued his researches. He was not able to make any long distance

Digitized by Google

practical experiments until July 1, 1908, when we began commercial wireless telegraphy. Nevertheless he made great progress by many inventions and improvements during his laboratory researches, and when we adhered to the Berlin Wireless Convention of 1906, we were able to open many public wireless stations at once, in accordance with his design and system. The wireless system is generally known as the Teishinsho system, or the system of the Department of Communication, for his laboratory as well as all commercial wireless stations in Japan belongs to this department.

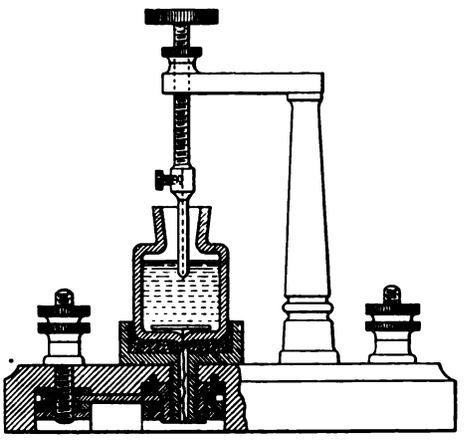

FIG. 2.—TANTALUM DETECTOR. FIGURE FROM THE JAPANESE PATENT SPECIFICATION No. 15,238 (1908).

Dr. Asano had many assistant engineers and among them Mr. Matsunosuke Matsushire and Mr. Mitsuru Saiki, especially the latter, gave great assistance in the work. Mr. Saiki is the most experienced and able wireless expert in Japan, and is the inventor and patentee of many inventions forming the most important details of the Teishinsho system now practically used in all stations.

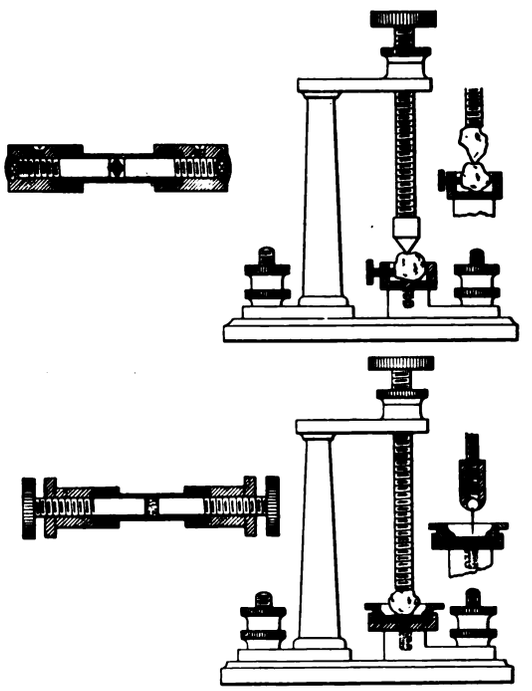

FIG. 3.—KOSEKI DETECTOR. FIGURE FROM THE JAPANESE PATENT SPECIFICATION No. 15,345 (1908).

All telegraphy and telephony in Japan are the monopoly of the Government, as is also the wireless branch. Dr. Asano was sent as our chief delegate to the Berlin Wireless Conference of 1906, and the Convention was fully ratified in our country. We have now five land stations and 11 ship stations, all open to the public day and night. Our commercial wireless business only began on July 1, 1908, and we are now about to instal many ship and land stations.

All the wireless installations and business are strictly in accordance with the Berlin Convention. The power used in our ship-stations is now generally 1 kw. or 1½ kw., and the maximum distance for regular direct communication between land and ship stations is nearly 1,500 miles at night and 400 miles in the daytime. All American liners with our wireless system, during their whole voyage of about 30 days between Hong Kong, Yokohama and Seattle or San Francisco, communicate directly with some land stations nearly every night; though this is generally impossible for one night (and sometimes for two nights) midway between Yokohama and Honolulu, which are 3,400 miles apart.

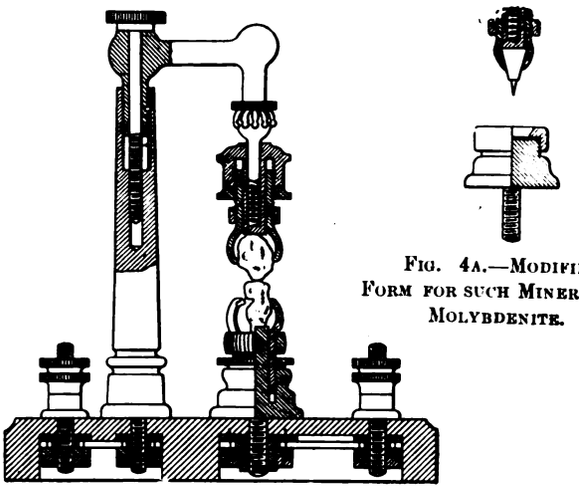

FIG. 4A.—MODIFIED FORM FOR SUCH MINERALS AS MOLYBDENITE.

FIG. 4. —KOSEKI DETECTOR.

The Teishinsho system is a spark system as regards its transmitter, and makes use of a telephone and detector for its receiver. Many special devices are used to minimise the damping and to get sharp tuning. Generally, the alarm device is not used, but the receiver is so arranged that we can use, by switching, either of two sets, one of which is arranged to be very acute in its tuning, but the other to respond to any waves over a certain wide range. All wireless stations are designed to use 300 metres as a standard wave length, and, by using the acute tuning set, we were able to cut off one wave from the other when the difference of the wave length reached 2 per cent. When we sent two signals simultaneously, with wave lengths of 300 and 306 metres respectively, from two stations in Tokyo, we received these two signals quite distinctly and independently with two receiving sets connected to one and the same aerial in Choshi station, about 60 miles from Tokyo.

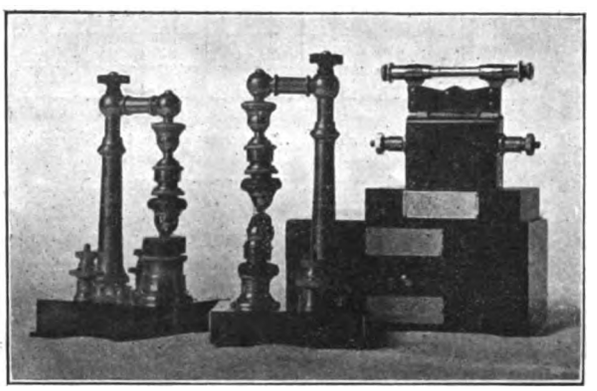

FIG. 5.—KOSEKI DETECTORS, PRACTICAL FORMS USED.

There are many kinds of detectors used in the system, but the following three have been the most successful: the Teppun detector, the tantalum detector, and the Koseki detector.

The Teppun Detector.—Up to about six years ago, a kind of mercury detector, devised by Dr. Asano, was used in many

Digitized by Google

researches, but the Teppun detector is the first one used practically in our commercial wireless business. This detector was devised by Mr. M. Saiki, and was patented by him (Japanese patent No. 11,849). Fig. 1 shows the construction of the detector. Two steel poles are magnetised and arranged to be adjustable in their distance as in a coherer. Fine steel powder, oxidised on its surface by burning in a flame, is introduced between the poles, so that the powder makes a bridge between them by the magnetic field of the poles. The powder must not be in too great a quantity, and each granule must be neither too large nor too small. The sensibility of the detector depends mainly upon the degree of the oxidation and also upon the adjustment.

The adjustment of the detector is not so difficult, and when once adjusted, the position may be fixed by screws.

The detector, thus adjusted, is very sensitive and quite stable. The end of the steel pole must be well polished and there must be no rust. The stronger the magnetic force of the poles the better is the result, and the use of the magnetic force to arrange the steel powder is the best feature of this detector.

The Tantalum Detector.—The tantalum detector is quite different from that of Mr. L. H. Walter who used a tantalum

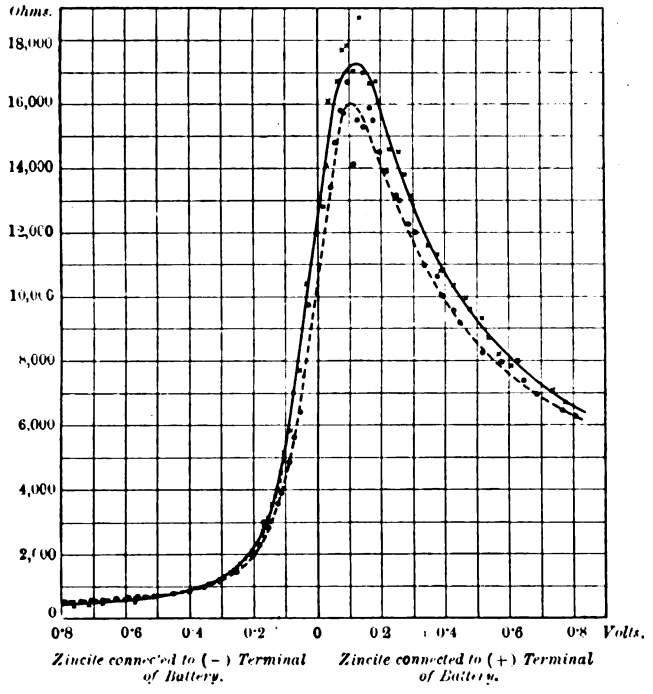

FIG. 6.—ZINCITE COUPLED WITH BORNITE.

point and mercury. Fig. 2 shows the construction of the detector. The device was invented by the writer, and was patented by him in Japan during 1908 (Japanese patent No. 15,238).

My tantalum detector depends upon dipping a tantalum point into some alkaline or acid solution. My first attempt was to get some detector utilising the rectifying property between some substance and vapour or solution. Mercury vapour was the first to be tried, for more than a year, but it gave no successful result as a sensitive detector.

The second idea was to utilise the aluminium rectifier, which is based upon some special insulating film between the aluminium and the solution. Various kinds of aluminium and aluminium alloy, as well as solutions, were tried, but though we got some result it was not so sensitive.

Besides aluminium, I tried many metals, like magnesium, which will give some rectifying phenomena, and finally arrived at tantalum. The rectifying property of tantalum is far quicker and more distinct than that of aluminium. Although the resistance in the direction of solution to tantalum is very low, that in the direction from tantalum to the solution is very high, and sometimes even a few hundred volts will scarcely produce any current.

The tantalum rectifier is quite sensitive as a wave detector. The surface of the tantalum may or may not be small, but a fine point like the platinum point in an electrolytic detector seems to be far the most sensitive. The principle of the tantalum detector is not yet proved, and there is some question whether the action as a detector is entirely due to the rectifying property of the insulating film or to phenomena something like the platinum point electrolytic detector as well as the rectifying property. The action of the tantalum detector with mercury, which seems to be another form of the utilisation of the surface tension of mercury, is quite different from this tantalum detector.

The tantalum detector is very sensitive, and many samples which I made in my laboratory were more sensitive than the glass-shielded platinum-point electrolytic detector. The tantalum is not acted upon by ordinary acid or alkali, and the life of the detector is very long.

Koseki Detector.—The Koseki detector, or mineral detector, was invented by the writer and was patented by him in Japan during 1908. The first idea underlying the investigation of minerals was the utilisation of magnetite as a powder in Mr. Saiki's Teppun detector. The degree of oxidation of the iron powder used in the detector has a great effect on the sensibility. Not only does it require skill, but the powder becomes more and more oxidised in the air, and finally becomes quite insensitive.

We tried to use natural iron oxide or magnetite instead of the

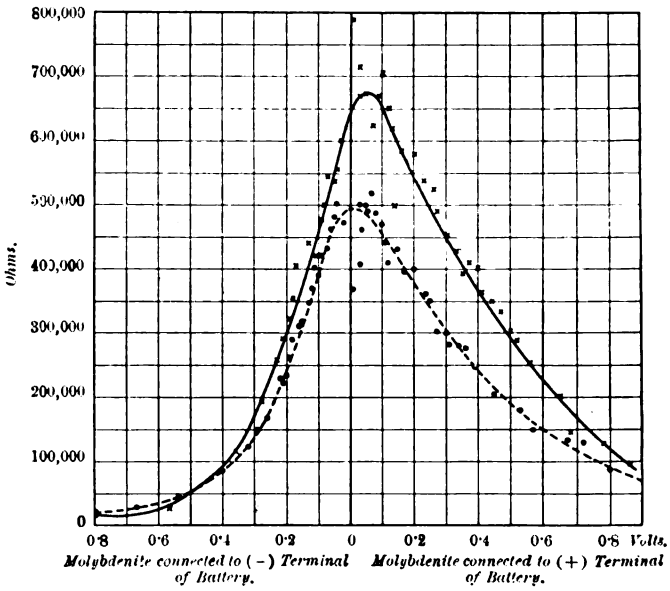

FIG. 7.—MOLYBDENITE COUPLED WITH BORNITE.

artificial oxide, and we found that magnetite is quite sensitive and durable when used as powder in a detector.

Besides magnetite, we found pyrohotite, arsenical pyrites, chromite, ilmenite, wolframite, iron glance, marcasite, &c., all quite satisfactory as a substitute for the iron powder in the Teppun detector. Mr. Saiki especially made an extensive investigation on the utilisation of ilmenite, and he found the ore very sensitive when used as powder, especially when used as a small piece burnt and pressed between the poles.

The sensibility of these iron ores depends upon the impurities in them, and therefore ores of the same kind have different sensibilities according to the mines where they were produced. Some of them are magnetic but others are not. Iron ore, which is not magnetic, is also quite sensitive as a powder or a block when used between two metal electrodes.

I tried about 200 kinds of minerals and found zincite, molybdenite, pyrolusite, iron pyrites, cassiterite, galena, &c., all very sensitive as wireless detectors, and the patent for the utilisation of these minerals which I thought to be the best was filed on August 12, 1908, and was granted on December 8, 1908, to the writer in Japan (Japanese patent No. 15,345).

Afterwards I made thorough investigations with Mr. E. Yokoyama, one of the electrical engineers in my laboratory,

Digitized by Google

on all the mineral samples in the Mineral College of the Tokyo Imperial University, and we found that the following ores are quite responsive to electric waves :—

1. Ores quite sensitive with perfect contact.

(*a*) Oxides:—
Simple oxides:
Zincite.
Tenorite or melaconite.
Cassiterite.
Anatase.
Arkansite.
Pyrolusite.
Wad.
Complex oxides:
Micacious hematite.
Ilmenite, iserine, hystatite.
Magnetite.
Psilomelane.

(*b*) Sulphides :—
Simple sulphides:
Molybdenite.
Galena.
Zinc-blende.
Chalcosine.
Iron pyrites.
Pyrrhotine.
Complex sulphides:
Nagyagite.
Tennantite.
Enargite.
Boulangerite.
Schwatzite.

(*c*) Metallic combinations :—
Lollingite.
Meteorite.
Smaltite.

2. Ores sensitive with a light contact

(*a*) Sulphides :—
Simple sulphides:
Marcasite or kyrosite.
Covelline.
Complex sulphides:
Siegenite.
Copper pyrites.
Cobaltite.
Ullmanite.
Bornite.
Sylvanite.
Arsenical pyrites.

(*b*) Metallic combinations :—
Niccolite.
Domeykite.
Strutterudite.
Allemontite.
Iridosmine.
(*c*) Native elements :—
Graphite.
Arsenic.

Nearly all ores with good conductivity can be used as a detector, but some of them require very light contact and

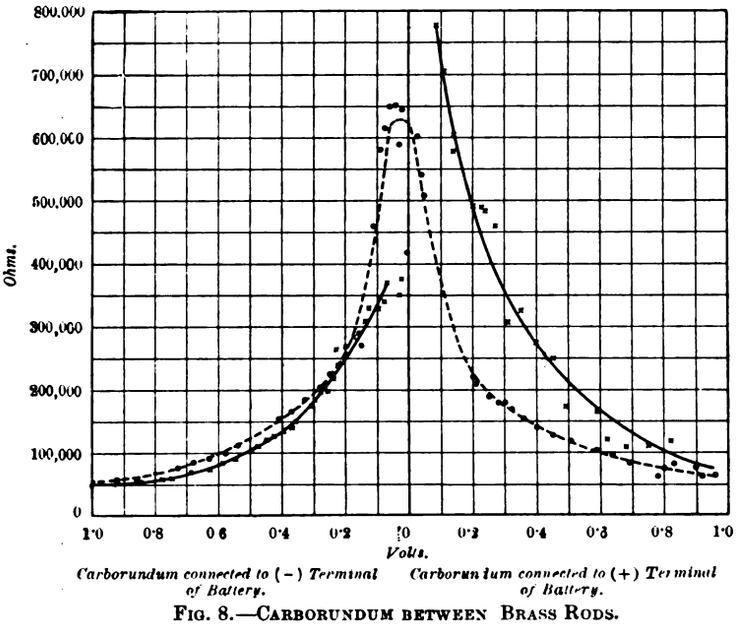

FIG. 8.—CARBORUNDUM BETWEEN BRASS RODS.

delicate adjustment and are not practicable. The action of mineral detectors seems to depend upon the chemical and physical properties of the ores, and also upon the condition of the contacts, but not upon the crystalline structure and axis of the ores. Generally the resistance of copper pyrites is very low and that of zinc-blende is very high, and they cannot be used as practical detectors when they are inserted alone between two metal poles, but their well-tarnished surface acts as a very sensitive detector. The zincite which I got at first time was a fine hexagonal crystal, and had the following component :— 93·9352 (ZnO), 5·0775 (Mn_2O_3), 0·5748 (FeS), 0·4125 (SiO_2). I tested the sensibility of the zincite by various methods, but could not find any difference depending on the axis of the crystal.

Fig. 3 shows the method used to test all minerals, and Figs. 4 and 5 is the actual form of Koseki detectors practically used in our commercial stations.

Every ore was tested in contact with a number of other ores as well as metals. Molybdenite does not give so distinct a result, but zincite gives a marked effect according to the ore in contact with it. Generally speaking, crystals which conduct electricity and heat very well seem to give better results than metals or other ores. Bornite, copper pyrites, or iron pyrites, give excellent results when in contact with molybdenite or zincite, especially with the latter. Copper pyrites and bornite are nearly equally good, but we always get better results with bornite. Bornite alone cannot be used as a detector, but when used with other minerals or crystals it greatly increases the sensibility. Mr. Saiki has devised the use of bornite with carborundum. The carborundum detector, which was invented by General Dunwoody, is very sensitive when used in contact with metals or carbon, but it is further improved by the use of bornite.

Molybdenite or iron pyrites make a very sensitive and practical detector when merely brought in contact with a metal point, such as platinum, steel, brass, &c.

As far as my experiments have gone, the zincite and bornite detector is the most sensitive, but is spoilt by strong waves and even by the induction from the sending waves of its own station. On the other hand, molybdenite and iron pyrites are not so sensitive as zincite but very steady, and are not affected by strong waves. The sound received with zincite is very loud ; that with molybdenite is not so loud, but both of them seem to respond to waves until the sound falls below the limit of sensibility of the human ear. Some kinds of detector give a very loud response when the energy received is within the limit of its sensibility, but no response at all after that limit. This

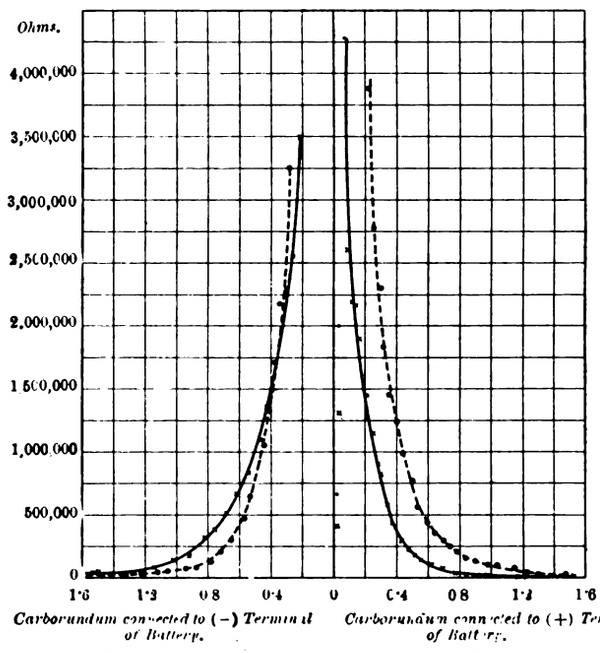

FIG. 9.—CARBORUNDUM COUPLED WITH BORNITE.

phenomenon was never experienced in the Koseki detector, and in some practical experiments between a land station and a ship leaving shore, those with sensitive ears were still able to hear when other people had ceased to perceive any signals. Magnetite, ilmenite and other iron ores may be used practically as detectors, but are much inferior to zincite, molybdenite and iron pyrites, both in sensibility, stability and durability. Following these investigations the use of zincite, molybdenite, iron stones, and mangan stones was claimed in the Koseki patent.

I found afterwards that Mr. Braun, many years ago, had made extensive investigations on various crystals, and also that Mr. G. W. Pickard is using the " Perikon " detector. The Perikon detector (U.S. trade mark No. 70,587) seems to have been the name given to the detector using the artificial solid solution of zinc oxide in readily fusible silicate (U.S. patent No. 886,154), and now the same name is used for the detector

Digitized by Google

with zincite and copper pyrites (U.S. patent 912,726), patented February 16, 1909, by Mr. Pickard in the United States of America.

The volt-ohm curves of these detectors are given in Figs. 6 to 9. The detectors were adjusted to the most sensitive positions and then, without disturbing the conditions, the local voltage was gradually increased to 1 volt and then decreased to 1 volt in the opposite direction, and was again increased to zero voltage. The terminal voltage was accurately measured by the condenser discharge method, and the current through the contact by a sensitive galvanometer. The resistances calculated from these data are not always constant, even with the same local voltage. Thus the volt-ampere curve got is something like a hysteresis curve for iron. Generally the steepest point of these curves seems to be the point for the best local voltage.

It will be the best practice to arrange molybdenite and zincite so that either can be used by switching over, and to use the former for the short distance and the latter for longer distances, and when the signal is very faint.

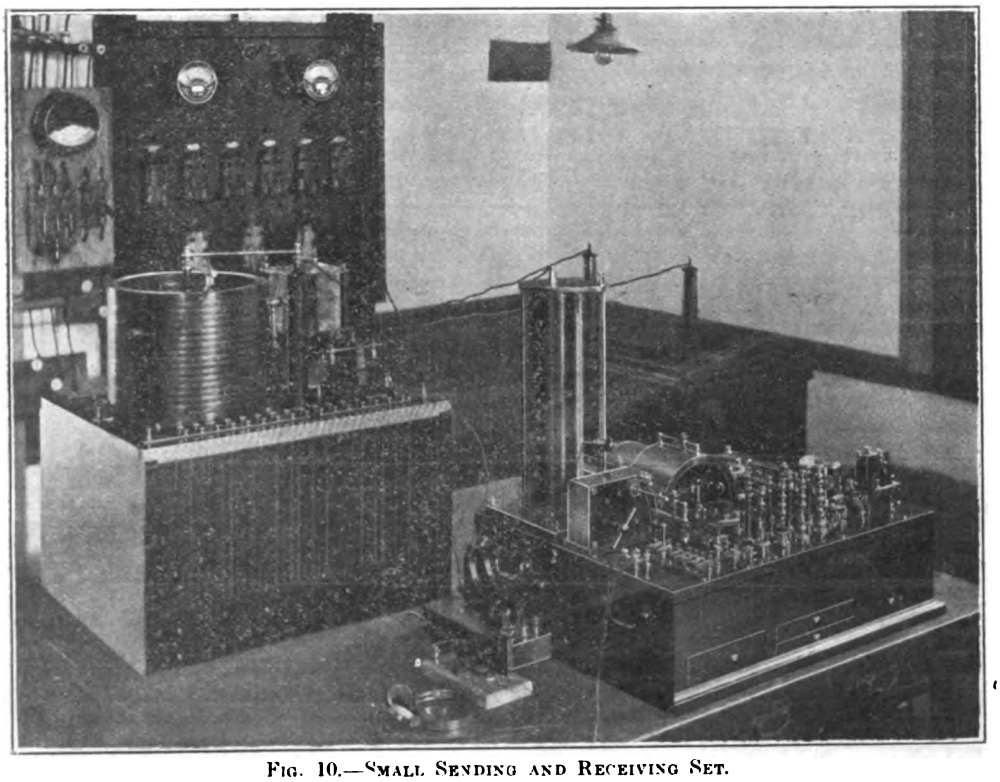

Fig. 10.—Small Sending and Receiving Set.

The wireless business in Japan is quite young, but even now, besides 11 Japanese ships with wireless, three ships with Marconi wireless and two ships with United wireless are coming every month to the Japanese coast. Moreover five more Pacific liners it is said are going to be installed with United wireless.

The communication between Hawaiian Island and the Pacific coast of the American Continent is quite easy even now, and it is said that the Kahuku station in Hawaiian Island has received signals from the Japanese coast during several months. When I was in Honolulu last September, I arranged to carry out experimental wireless communications between the Kahuku station and Japan. The distance between them is nearly 3,400 miles. The power used in Japan coast stations is all below 5 kw., and the signals with such a small power are said to have been transmitted over so great a distance as 3,400 miles. The power used in Kahuku station is 15 kw., and by arranging to make tests when both stations were quite dark, we carried out experiments twice last November and December.

Although we made the test very carefully, we were not able to get any result at either station, but we succeeded in receiving the ss. "Korea," which has occasionally called up the Kahuku station from the position (latitude 22° 23′ longitude 160° 30′), about 300 miles from Honolulu near Japan. Korea has a 5 kw. United wireless installation and sent her signals quite distinctly over 3,160 miles. We hope to make further experiments with increased power, and to establish the regular trans-Pacific wireless communication between Japan, Hawaiian Island and the Pacific coast of the American continent, and this third test will be made in the immediate future.

THE LAWS OF ELECTROMECHANICS.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

In recent times many applications have been made of electricity to mechanism, by devices the earliest and simplest of which is the electromagnet. Mechanical movement is produced, or mechanical force is exerted in these mechanisms by switching on an electric current. The object of this brief communication is to present a simple summary of the laws which govern such electromagnetic apparatus, and to point out some of the relations between them.

In every electromagnetic apparatus or mechanism there are two parts—an electric circuit and a magnetic circuit—and these two are interlinked. This interlinked system in every case presents a certain initial configuration, the electric circuit being more or less interlinked with the magnetic circuit, and each circuit having its own configuration or disposition of parts. Whenever an action is produced in such a system there is some change of the configuration of the system as a whole, the change of configuration being such as to alter the amount of interlinkage between the two circuits which constitute the system. Let C stand for the amount of current (in C.G.S. units) in the electric circuit, let N stand for the amount of flux (*i.e.*, number of magnetic lines) in the magnetic circuit, and let S stand for the number of times that the electric circuit is interlinked with the magnetic circuit. Then the potential of the system is proportional to C, to N and to S severally, and is therefore proportional to the product CSN. The general law of electromechanics may then be stated as follows:—

Every electromagnetic system tends so to change its configuration that the product CSN tends to become a maximum. In other words, every electromagnetic system tends so to change its configuration as to bring about the greatest possible amount of interlinkage of the current in the electric circuit with the flux in the magnetic circuit.

The three quantities C, S and N are connected by certain physical relations as follows:—

(i.) *Law of the Magnetic Circuit.*

$$N = \frac{4\pi CS}{Z}, \quad \ldots\ldots\ldots \quad [I.]$$

where Z is the quantity commonly called the reluctance of the magnetic circuit, and is dependent on the configuration and materials (iron, air, &c.) of which the magnetic circuit is composed. If there be no magnetic leakage, that is, if the entire magnetic flux is interlinked with the entire electric current any integral number of times, then S, the numeric of interlinkage, is the same thing as the number of turns or spirals of the conductor which carries the current. If there is magnetic leakage, then the numeric of interlinkage is less than the actual number of turns.

*Abstract of a Paper read before Section G of the British Association at Sheffield.

Digitized by Google

(ii.) *Law of Induction* (Faraday).

$$E=-\frac{dN}{dt} \text{ in one turn.} \quad . \quad . \quad . \quad . \quad . \quad . \quad [II.]$$

or $$E=-S\frac{dN}{dt} \text{ in S turns,} \quad . \quad . \quad . \quad . \quad . \quad . \quad [II.a]$$

where E is the E.M.F. induced in the electric circuit by a change in the interlinked flux such that during the time dt the flux decreases by the amount dN.

(iii.) *Law of the Electric Power.*

$$\frac{dW}{dt}=-CE, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [III.]$$

where dW is the amount of work done by the electromagnetic system in changing its configuration during the time dt, and E is the counter electromotive force developed during the movement.

(iv.) *Law of Work.*—Combining (ii.) and (iii.) we get

$$\frac{dW}{dt}=CS\frac{dN}{dt}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [IV.]$$

whence $$dW=CSdN, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [IV.a]$$

or, if CS be constant and N independent of C, we have

$$W=CSN. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [V.]$$

If any change of configuration occurs such that the initial flux N_1 is altered to the value N_2, then the work done by the system in this operation is

$$W=CS(N_1-N_2). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [V.a]$$

The general law of electromechanics, stated at the outset, may now be restated in the form that, C and S being constant, the system tends so to change its configuration the potential energy shall be a minimum, or that N_2-N_1 shall be a maximum. If S is not constant, then if S_1N_1 be the original amount of flux interlinkage, and S_2N_2 the final amount, the law may be stated in the form that the system tends so to change its configuration that $S_2N_2-S_1N_1$ is a maximum.

The law of work may be written also

$$W=\int CSdN, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [V.b]$$

and if CS is constant and N is an independent flux, the integral is simply W=CSN, as above. But if N is due solely to C, the integral has the value

$$W=\tfrac{1}{2}CSN.$$

(v.) *Law of Change of Flux.*—Any change in the configuration of the magnetic circuit produces a change in the reluctance, and the change in reluctance produces in turn a change of flux. The relation can be found by differentiating the equation for the flux (i.) with respect to the reluctance; giving us the result

$$dN=-\frac{4\pi CS}{Z^2} \cdot dZ.$$

Combining this with [IV.a] we get

$$dW=-\frac{4\pi C^2S^2}{Z^2}dZ \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [V.c]$$

$$=-\frac{N^2}{4\pi}dZ. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [Vd.]$$

In many electromagnetic systems, over a considerable part of the range of action the flux is nearly constant owing to magnetic saturation of the iron core, and in these cases dW will be practically proportional to $-dZ$. It also follows that for a given small change of reluctance, the work is proportional to the square of the flux present.

(vi.) *Law of Force.*

$$f=\frac{dW}{dx}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [VI.]$$

whence $$f=-\frac{4\pi C^2S^2}{Z^2}\frac{dZ}{dx}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [VI.a]$$

where f is the force and dx the elementary displacement. If C and S are constant, the force is dependent on the change of reluctance per unit of displacement, and is inversely proportional to the square of the reluctance. Another expression for the force, derived directly from equation [IV.a] is

$$f=\frac{dW}{dx}=-CS\frac{dN}{dx}; \quad . \quad . \quad . \quad . \quad . \quad . \quad [VI.b]$$

that is—assuming C and S constant—the force is proportional to the rate of decrease of the flux per unit length of the displacement.

In predetermining the performance of any piece of electromagnetic mechanism, the chief difficulties arise in estimating the probable values of the reluctance Z and of the numeric of interlinkage S. The value of this latter, as stated above, diminishes with magnetic leakage. Some assistance is afforded by considering the quantity called "coefficient of self-induction" and usually denoted by L. This coefficient is nothing else than the total interlinkage per unit of current, or in symbols,

$$L=\frac{SN}{C},$$

whence, if L and N are experimentally determined, S can be deduced. Substituting for N its value $4\pi SC\div Z$,

$$L=\frac{4\pi S^2}{Z} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [VI.c]$$

Various curves of performance have been given, by different authorities, for the pull of electromagnetic solenoids. These curves agree fairly with the predetermined values for those positions of the plunger where the reluctance is small, but differ often rather widely for large values of the reluctance. The discrepancy is traced to the assumption that S, the numeric of interlinkage, is usually assumed to be the same as the number of turns and to be constant.

ON THE USE OF AN ACCELEROMETER IN THE MEASUREMENT OF ROAD RESISTANCE AND HORSE-POWER.*

BY H. E. WIMPERIS, M.A.

Summary.—The author describes the construction and principle of the accelerometer which he has designed, and by means of which road resistances can be measured and compared. Some interesting figures are given in this connection.

The need has often been felt for some small portable instrument which would measure the resistance to the motion of any moving vehicle or train of vehicles, and enable a calculation to be made of the horse-power necessary for propulsion. If an instrument could be obtained which would show the negative acceleration of a vehicle when "coasting" with the power cut off, it would be quite easy to deduce from its readings the total amount of the force due to the resistances to motion. Those resistances are, of course, air resistance, road surface resistance and resistance due to the friction of the mechanism in motion. To measure these resistances the instrument used must be sensitive to very small accelerations, and must give a steady reading of the needle even when the jolting of the vehicle is considerable.

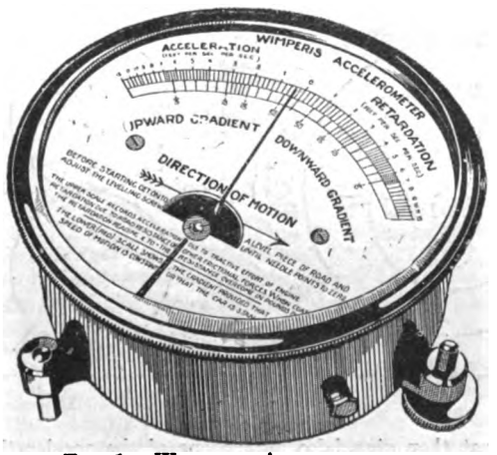

FIG. 1.—WIMPERIS ACCELEROMETER.

The instrument described in this Paper was designed by the author, and brought to a high state of mechanical perfection with the experienced aid of Messrs. Elliott Brothers, whose valuable assistance it is a pleasure to acknowledge. The general appearance of the instrument† is seen in Fig. 1, and a diagrammatic representation of its mechanism is given in Fig. 2. To make a measurement of the tractive effort necessary to overcome the resistance to motion the instrument is levelled on the floor of the car by means of the adjustable leg, and then, when the car is coasting, the indication of the needle gives the reading in "pounds per ton."

The general nature of the internal mechanism may be described as a lop-sided copper disc, mounted on a vertical axis and controlled in its rotation by a coiled spring. Any acceleration causes the heavier side of the disc to lag behind, and so partially wind up the spring. The degree to which the spring is wound up measures the acceleration. Any tendency of the disc to oscillate is checked by

* Abstract of a Paper read before Section G of the British Association.

† A brief description of the instrument appeared in THE ELECTRICIAN, November 19, 1909.

Digitized by Google

a magnetic field at right angles to the plane of the disc. Besides these parts, there is what is called "the compensating balance," which causes the instrument to record absolutely correctly, even when travelling around railway curves, or when on a road heavily cambered to one side or the other. In Fig. 2 the copper disc is shown at D; it has a hole cut in it near the circumference, which has the effect of throwing the centre of gravity slightly out of the centre of figure. On the pivot of the disc is fastened a spur wheel which gears in with another equal spur wheel mounted on a parallel axis and carrying the pointer N. This pointer moves over the scale shown in Fig. 1. It will be seen that there is a small permanent magnet placed so as to "damp" the motions of the copper disc without having any of the "sticking" qualities which accompany frictional damping. The spring, which is coiled up by the rotation of the disc, is not shown, but it lies in the horizontal plane just above the disc. In later forms of the instrument the arrangement described above has been varied slightly, but not so as to affect in any way the general principle of working.

The forces acting at the centre of gravity of the disc are directly proportional to the impressed acceleration, but as the disc rotates through angles of 30 deg., 45 deg., 60 deg., &c., the "arm" gets less, and the couple twisting the spring does not rise so rapidly as the acceleration producing it. The scale has to be graduated in accordance with this fact, and the divisions close up when the angles get considerable. The law which governs this is that of the change of the ratio $\frac{\theta}{\cos\theta}$.

As to the mode of action of the compensating device, if, whilst the disc is deflected by an acceleration, a second acceleration (or slope) should be acting at right angles to the first, there will be an additional couple tending to wind (or unwind) the spring. The

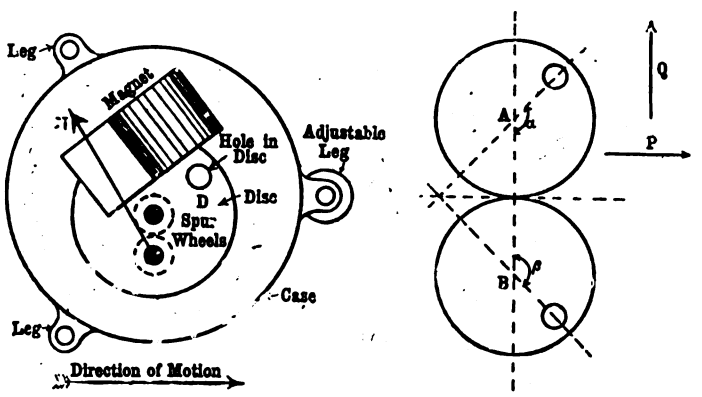

FIG. 2.

needle must then give false indications of the acceleration which it is desired to measure. This would be a very serious fault, since such transverse accelerations are very common in practice and often of considerable amount, sometimes as much as 10 ft. per second per second. (This type of error is noticeable in the pendulum forms of instrument, where the complicating vertical acceleration often far exceeds that of gravity itself.) To get over this difficulty the two gear wheels, already mentioned, were added, and it was so arranged that the moments of mass about the two respective axes should be equal. This equality of mass moments makes the system equivalent to two equal copper discs geared together at their circumferences, and each having their centres of gravity eccentric to the same extent. The effect of this is illustrated in the diagram to the right-hand side in Fig. 2. Inspection of this diagram will show that forces in the direction P will cause the two discs to roll together, whilst forces in the direction Q cause no rotation whatever. Forces perpendicular to the paper can, of course, produce no rotation of the disc, so that the instrument records the acceleration in one of the three directions of space only, and is not affected by whatever may be happening in the other two. Thus, the dial may even be tilted until it is vertical, so that the whole force of gravity acts across it without the readings being affected at all. The author believes that this is the first accelerometer instrument to read in one selected direction only.

It is evident that when the instrument is tilted in the direction of motion the needle will move through an angle corresponding to the angle of tilt, and this angle can be read from the (red) graduations on the dial. The instrument thus becomes a "gradometer," and it has the property that it can be used just at well for this purpose on a car which is climbing a slope as on one which is standing on the slope, always provided that the speed of the car is uniform. Although the instrument is thus sensitive to slopes, it is the fact that the "coasting resistance" readings do not need correction on account of the measurements having been made up or down hill. This appears at first sight surprising. The explanation is, however, that when coasting down a hill the slope tends to throw the needle forward, whilst the gravitational acceleration due to the slope throws it in the opposite direction, and by just an equivalent amount, so that the two effects neutralise one another; and were there no road resistance whatever the instrument would indicate zero. What, in practice, causes the needle to move away from the zero mark is the frictional resistances due to motion. The needle, therefore, shows the amount of this resistance, no matter whether the motion of the car is on a sloping road or not.

As a matter of practical convenience, it is best to make such measurements when on a slight downward slope of from 1 in 30 to 1 in 60, the reasons for this being that the speed then changes more slowly, so giving a longer time for taking the readings, and the complicating effect—so well known to railway engineers—of the change in the momentum stored in rotating parts is then insignificantly small. It may be mentioned that if the rotational momentum is c per cent. of the translational momentum, the true road resistance is c per cent. higher than that deduced from the negative acceleration induced by that resistance, and shown on the dial of the accelerometer, when running on a level road. When the road is not level the instrument reading shows the acceleration, or retardation, directly due either to the engine, to the brakes or to the road resistance (or a combination of them), and in all cases where these measurements are desired a knowledge of the slope is unnecessary (a proof of this is included in the Paper).

Whatever may be happening to the car the instrument records the net effect of engine effort, braking resistance and road resistance, and is not affected by hill slope. This fact it is that renders the instrument capable of reading the slope of any hill up which the car may be climbing at a steady speed, since the braking effect is then zero, and the reading is the difference between the effort of the engine and the road resistance. This amount must, however, be equal to the gravitational resistance overcome, or the speed would not be steady, and as the gravitational resistance is directly proportional to the steepness of the slope, it follows that the instrument reading is also proportional to that steepness.

Train and Road Resistance.—Many measurements with this instrument have now been made on roads and on railway lines; in the latter case a very fine spring is fitted, and readings can be made to ½ lb. per ton. In a recent case the author measured the train resistance at about 65 miles per hour as from 19 lb. to 21 lb. per ton, rising to 30 lb. on some curves and sinking to 10 lb. at about 10 miles per hour.

Table I. shows the results of a number of tests taken with the accelerometer on different kinds of road surface. Measurements of this kind are rare, since the dynamometer method of measurement is very clumsy, and is liable to inaccuracy if the slope of the road is incorrectly estimated. The present measurements are free from that type of error. Muddy roads, as might be expected, show higher resistance than dry ones, but the low resistance on granite setts would hardly have been anticipated, nor the great increase in resistance when travelling over sticky tar macadam roads with plain flat steel tyres. The author has not yet had opportunity to make measurements on pneumatic tyres which are comparable with any of these. So far as tests are available, however, they do not show any very great difference in the road resistance between these two types of tyre.

A series of tests taken on motor vehicles when running at different speeds on good hard main roads are also given in the Paper. Table II. herewith contains some of these figures.

The rise of resistance at higher speeds due largely to the growing importance of air resistance is very noticeable. To the author it was so unexpected that a waggon running at 15 miles per hour should be appreciably affected by air resistance that he at once attributed the rise to some other cause to be ascertained. Part of the rise is, no doubt, due to a term proportional to the speed and corresponding to the loss of energy through the bumpiness of even the best roads. The simplest formulæ to suit these curves are, however, of two terms only—a constant term and a term proportional to the velocity squared. Thus, for the motor waggon, if we call the resistance overcome at the clutch R in pounds per ton, we find that $R = 38 + 13\left(\frac{V}{10}\right)^2$, where V is speed in miles per hour. Also, for the touring car, $R = 47 + 11{\cdot}5\left(\frac{V}{10}\right)^2$. The author hopes to obtain values of these coefficients for various shapes of body, hood and screen.

Curves of brake horse-power based on the resistance at the clutch are given in the Paper. As the engine friction is well known to be independent of the load, provided the speed is constant, it is possible

Digitized by Google

Table I.
Condition of wind on these various tests differed on each, but fairly still days were chosen.

Nature and condition of road.	Coasting resistance (declutched), lb. per ton.	Approx. speed, m.p.h.	Nature of motor vehicle.	Tyres.
Tar macadam, hard...	65	10	Motor waggon, total weight loaded 4·3 tons	Steel behind, solid rubber in front
Ditto, soft and cut-up	140	10		
Granite setts.....	50	10	Ditto	Ditto
Hard, dry main road	73	15	Heavy touring car total weight loaded 2·25 tons	Solid rubber
Half rolled road metal	150	15	Ditto	Ditto
Clean wood pavement with tram lines	70	10	Motor waggon, total weight loaded, 4·35 tons	Ditto
Tar macadam, dry and hard	70	10	Ditto	Ditto
Ditto, very muddy and sticky	95	10	Ditto	Ditto
Road metal, partly rolled	120	10	Ditto	Ditto
Ditto, unrolled.....	200	10	Ditto	Ditto

Table II.—*Coasting Resistance at Various Speeds on Heavy Touring Car fitted with Solid Rubber Tyres.*

Total weight loaded 2·25 tons. Car fitted with fixed canopy, glass screen (in use) and side curtains (end and last pair of side ones down). Engine speed at 20 m.p.h. = 970 revs. per min. Tests taken against a slight head wind. Roads good and hard.

Speed, m.p.h.	Coasting resistance in pounds per ton.		
	Ignition off.	Clutch out.	Neutral gear.
5	60	50	46
10	71	59	53
15	87	73	63
20	111	92	76
22	122	101	82
25	...	118	92
30	...	...	112

to calculate the indicated horse-power from the "ignition off" curves. The ratio of brake horse-power to indicated horse-power at any speed is, of course, the mechanical efficiency of the engine. The mechanical efficiency can also be obtained as the ratio of the height of the resistance curve when "declutched" to the height with "ignition off." It also follows that on any such test as those described a measurement of the amount of fuel used will enable a figure to be obtained for the mean thermal efficiency of the engine during the run. The figure in these tests came out at about 12 per cent., but it varies, of course, with the individual circumstances of the test; by keeping the speed nearly constant a good brake-efficiency test can be got under much more real conditions than on a test bench.

The horse-power is obtained from the road resistance and speedometer measurements from the following formula.

$$\text{H.P.} = \frac{\text{road resistance in lb. per ton} \times \text{car weight in tons} \times \text{m.p.h.}}{375}$$

After discussing engine friction and clutch resistance, the author sums up as follows:—

(1) By the use of the accelerometer the road resistance of different kinds of roads or tracks, under various weather conditions, can be measured and compared. (2) The amount of air resistance due to various forms of vehicle can be at once determined. (3) The mechanical and thermal efficiency of the engine at various speeds can be obtained under real working conditions. (4) The brake horse-power exerted by the engine when running at various speeds on the road can be easily obtained. (5) It is possible to trace step by step the losses of power in transmission. (6) It is possible to make a definite allowance for motor vehicles which are specified to show a given fuel economy (such as gross ton-miles per gallon of fuel), and which may have to run their tests on exceptionally heavy roads. (7) Lastly, the use of the accelerometer enables a useful interpretation to be given to speed and efficiency tests which are carried out on specially prepared motor tracks, having characteristics different from those of the ordinary highway, at unrestricted speeds.

PHOTO-ELECTRIC FATIGUE.*

BY H. STANLEY ALLEN, D.SC.

The observation of Hertz in 1887 that the electric spark passes more readily when the spark-gap is illuminated by ultra-violet light led to the discovery by Hallwachs of the photo-electric current. A negatively charged body often loses its charge rapidly when exposed to light, especially to ultra-violet light. The discharge is due to the emission of negative electrons from the illuminated surface. The photo-electric activity of a freshly polished metal surface diminishes with the time, falling off rapidly at first, more slowly later on. This is known as the "fatigue" of the Hallwachs effect. In the early literature of the subject the fatigue was attributed to the direct action of the light, but Hallwachs showed in 1904 that fatigue proceeds in complete darkness, so that light cannot be the primary cause of the change. This result has been questioned, but is now confirmed by the experiments of Bergwitz, Dember, Ullmann and Allen. Light can, however, set up secondary actions tending to accelerate or retard fatigue. Hallwachs has shown that at ordinary pressures fatigue is more rapid in a large vessel than in a small one. This also was called in question by Aigner, but is confirmed by Ullmann and by Allen. The fatigue is practically independent of the electrical condition of the plate. This was shown by v. Schweidler, and has received confirmation in the researches of Hallwachs, Sadzewicz and Allen.

Experiments in a vacuum have led to contradictory results. Lenard and Ladenburg found marked fatigue in certain cases, while for the alkali metals, first investigated by Elster and Geitel, several observers conclude that there is no true fatigue. Recent experiments by Millikan and Winchester show no fatigue with clean unpolished metal surfaces in a very high vacuum. To explain the fatigue found by other investigators we must take into account the mode of preparation of the surface (Ladenburg's plates were polished with emery and oil), the difficulty of removing air films from the surface, and the possibility of changes in the gas pressure.

Various theories have been advanced as to the nature of the change accompanying photo-electric fatigue: (1) A chemical change, such as oxidation of the surface; (2) a physical change of the metal itself, as, for example, a roughening of the surface; (3) an electrical change in the formation of an electrical double layer (Lenard); (4) a disintegration of the metal, due to the expulsion of electrons by light (Ramsay and Spencer); (5) a change in the surface film of gas or in the gas occluded in the metal (Hallwachs).

Hallwachs has shown from the photo-electric behaviour of copper and its oxides that oxidation cannot be the cause of fatigue, and the fact that fatigue is less in a small vessel may be interpreted by attributing it to some substance (*e.g.*, ozone, water vapour) present in small quantities in the surrounding atmosphere. The results recorded lead to the view that the main cause of fatigue is to be found in the condition of the gaseous layer at the surface of the plate.

The Electrical Operation of Goods Trains.—Our contemporary the "Elektrische Kraftbetriebe und Bahnen" mentions that a standard gauge light railway at Gummersbach has recently been electrified. The railway is intended principally for goods and carrying ore, but there will also be a few passenger trains. High-tension three-phase current at a pressure of 10,000 volts and a frequency of 50 will be obtained from the local electricity works and transformed by two 150 kw. motor-generators to continuous current at 750 volts for supply to the trolley wire. The railway is 10 miles long, the maximum distance from the transformer station being 5 miles. The goods consist for the most part of stone from the stone quarries which is only carried in one direction, so that only fairly empty waggons have to be drawn against the gradient. Owing to this circumstance the average consumption on the continuous-current side is only 160 watt-hours per ton-mile. The goods trains, which consist of six standard open waggons, are drawn by locomotives weighing 20 tons and fitted with two 60 H.P. motors, without causing any great variation of load at the transformer station. A comparison between the two systems of working—steam and electricity—shows that the latter is more efficient in every way. The passenger traffic is dealt with by means of motor cars and trailers. The total cost of conversion from steam to electric working was £100,000.

* Abstract of a Paper read before Section A of the British Association at Sheffield.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.
(This charge includes all Supplements.)
Vols. I to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Allison T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d. [Price 10s. 6d. nett.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903). PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.* [Price 3s. nett.

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement will be published (Gratis) with the number of "THE ELECTRICIAN" for Sept. 23.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

POWER FROM WIND AND SOLAR RADIATION.

One of the important subjects looming in the future is that of the production of power from the wind and solar radiation. For the moment it is not a problem pressing for immediate solution, but there is little doubt that when the exhaustion of the coal supply in this and other countries begins to be an actual fact the question of other sources of power will be taken up in real earnest. Apart from the question of tackling the problem sooner or later from sheer necessity, it seems highly unsuitable that we should burn coal and other combustibles for the production of power if this is obtainable commercially from natural sources which are running to waste. The amount of power that is running to waste in sunshine and in the energy of the wind is enormous, but there has always been a difficulty in utilising this power in such a way as to give a truly commercial result.

The problem was raised last week at the meeting of the British Association by Prof. R. A. FESSENDEN, who claimed that he had now solved the problem in a commercial way. Briefly, his plan is to use the energy of solar radiation in combination with wind power, so that when one fails the other is likely to be at hand. It is, of course, no new thing to attempt the raising of steam through the agency of sunlight. Hitherto, however, attempts so made have restricted themselves to the production of the usual high steam pressures, such as 100 lb. per square inch or more, for use in reciprocating steam engines. Such attempts have not led to commercial results, and appear to be doomed to failure. The exhaust steam turbine, however, among its many virtues, holds out the possibility of another solution of the

Digitized by Google

problem before us. By taking advantage of this prime mover Prof. FESSENDEN makes use of steam at very much lower pressures: in fact, his suggestion is to raise steam merely at atmospheric pressure, and this at once gets over the difficulty of heating a boiler which has to withstand pressure. If the steam is used at the pressure of the atmosphere a thermal tank can be used with merely a covering of glass through which the solar radiation will pass and a large area of water will be exposed to its heating influence. The details proposed seem to be ingenious, but results are not given of actual working, so that it is difficult to judge of the practicability of such a scheme under actual working conditions. Unfortunately, there is no guarantee of continuous sunshine in any one day, at least in this country, and there is the further difficulty that more power may be required in the winter time when there is a minimum of sunshine than in the summer time when the sunshine is at its best. So far as this country is concerned, we must turn to the second proposition, viz., the utilisation of wind power. Here the difficulty is very largely one of storage. The most obvious system of storage is that by means of water, but the construction of reservoirs in elevated positions is generally a costly process, and therefore such schemes hitherto have not received serious consideration, though it will be remembered that a scheme of this kind was proposed in connection with the utilisation of the Victoria Falls. Prof. FESSENDEN proposes to get over this difficulty by placing his reservoirs underground instead of in an elevated position, the advantage being that the work of excavating a shaft to a depth of 1,000 ft. and making reservoirs at that depth is comparatively inexpensive.

Turning to the details given in the Paper we find it a little difficult to judge of the value of the scheme, as very few details are given, and the Paper seems to bear evidence of having been written in haste. There appears, for example, to be some confusion between horse-power and horse-power-hour, though we do not doubt that the distinction is perfectly clear to the author himself. A comparison is first made with storage by means of an electric accumulator. The statement is made that a lead battery costs approximately £10 per horse-power-hour. Considering that batteries for work of this kind—if the plant is capable of doing serious work—would have to be of considerable size, we think it will be admitted that this figure is unduly high. Even at a one-hour rating, including boosters and switchboard, the figure seems to be high, and when it is considered that a battery for this class of work would certainly not be used at the one-hour rate the figure is very much higher than need be taken. For this reason we think that £5 per horse-power-hour would be ample. We also notice that a charge of 10 per cent. on the first cost is to be made for depreciation, and a further charge is made for upkeep. This also is considerably higher than that at which battery companies are willing to maintain a battery subjected to ordinary station use. Then we notice that Prof. FESSENDEN provides storage for a fortnight. The amount of storage will, no doubt, depend very largely upon the locality, and we suppose that in some parts of the world it may be quite necessary to provide storage to this extent. In this country, however, a week would appear to be sufficient, though the allowance would, doubtless, have to be on the safe side. Even allowing storage for a fortnight the capital cost per horse-power-hour should be considerably less than the £140 taken by Prof. FESSENDEN. If we understand Prof. FESSENDEN aright, the annual charge of £26 which he mentions is for $\frac{1}{24}$ H.P. year, assuming a 24-hour day, and seems to us too high, though correspondingly low for 1 H.P. year, which is the usual unit.

With regard to the particulars of the cost given for the water-storage scheme, these are too scanty for a detailed criticism. We are inclined, however, to think that they are on the fine side, and they do not seem to be entirely accurate; for example, a cubic yard of water falling through 1,000 ft. does not give so much as 1 horse-power-hour, as assumed. The energy efficiency of a storage battery might be as low as 65 per cent. as assumed, though we should certainly expect to find it somewhat higher. Thus, Mr. J. S. HIGHFIELD mentions a case in which a station battery gave an efficiency of 74 per cent. over a period of 12 months. On the other hand, we are somewhat doubtful whether the efficiency, viz., 80 per cent., assumed for the water plant would be obtained when the necessary gearing and pipe work is taken into account. Final figures put the cost per horse-power-year at 18s. This, of course, is extremely low, and is compared with steam at £3 per horse-power-year, which is also extremely low, if not impracticable. Considering that the plant for utilising the energy of the water has to be practically duplicated in the form of a prime mover, pumps and pipe work, in order to bring the water to the required level for utilisation, it seems offhand extremely doubtful whether such a low figure could be obtained, even where the conditions are so favourable as to provide sea water at the foot of a cliff 1,000 ft. high.

We do not, however, wish to throw cold water upon such projects, and we are very glad to hear that Prof. FESSENDEN actually has a plant of 3,000 H.P. in hand, the site being a disused mine. Everyone will await the results with keen interest, though meanwhile we may perhaps be pardoned for being a little sceptical as to the results in the general case being quite so good as the figures that are suggested. Nevertheless, even if the results are not so good, there is no doubt that they will be important as a basis for further progress in a most fascinating subject.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Electrical Distributing Networks and Transmission Lines. By ALFRED HAY. (London: Cassell & Co.) Pp. xiii. + 234. 8s. 6d. net.

The subject is treated by this well-known writer from a technical and theoretical rather than a commercial standpoint. The arrangement of the subjects is excellent, and mistakes have been carefully guarded against. Every point dealt with has a boldly printed headline which permits of quick reference to the information desired. Each question dealt with by the author has his conclusions tersely put and printed in italics. It is a book more suited to the mains engineer and advanced student than to the beginner.

Glancing through the book, we notice that the use of "back E.M.F. cells" on short feeders is mentioned on p. 7. We

Digitized by Google

fancy that few, if any, generating stations use cells for this purpose. On p. 8 the effect that increase of the supply pressure has on the cost of the distributing system is very clearly shown, but the statement made on p. 23, that most types of metal filament lamps must be run two in series if the supply pressure is 200 volts or more, is incorrect.

The spirality effect of a stranded conductor when carrying alternating currents mentioned on p. 39 is very interesting and will be new to most readers. A few pages further on the question of aluminium as an electrical conductor as compared with copper is discussed. This question has aroused great interest of late. The distribution of electrical stress in the insulation of a cable and the effect that the shape and size of a conductor have on this is ably demonstrated on pp. 47 to 49. Mervyn O'Gorman dealt with this subject very fully in a Paper before the Institution some time ago. One of the advantages of tinning the conductors of a rubber-insulated cable is shown to be that the pure rubber in contact with the core does not deteriorate through the absorption of oxygen. This point should be investigated with regard to aluminium, which is much more liable to be oxidised on its surface than copper.

As might be expected from this author, the chapters on the effect of capacity, inductance and power factor on the working of an alternating-current network are especially good. The chapter on voltage drop and current distribution is not so good from a practical standpoint, as an engineer might spend a great deal of time arranging for a certain voltage drop on all parts of a network only to find that the variation of loads at different periods of the day, the wholesale adoption of metal filament lamps, or the unexpected increase of the heating or power load upset all his calculations.

It is rather a pity that the author has passed over fault finding on cable networks so briefly, and the same remark also applies to the chapter on the methods of laying cables. The chapter dealing with electrical resonance and surges will prove of great interest to those who are employed in high-tension alternating-current stations. The author states very clearly the precautions that should be taken in order to prevent the abnormal rises in pressure that occasionally occur on networks. He deals a little further on with the protection of high-voltage networks by means of maximum current and reverse-power relays, and shows how, unless these are arranged properly, sound feeders may be disconnected and rotary convertors, that are free from faults, cut out of circuit. The author concludes by describing the Merz-Price system of protecting high tension networks.

Of late years there has been such a universal scrapping of private electrical plants and changing over from steam and gas to electrical driving of machinery, that electrical distribution, especially high-tension, has become of great importance, and we therefore welcome the present volume.

W. A. TOPPIN.

Wireless Telegraphy and High Frequency Electricity. By H. L. V. TWINING. With a chapter on "Wireless Telephony," by WM. DUBILIER. (California: the Author.) Pp. 202.

This is a book for amateurs, written by an amateur. It is intended to appeal to all those whose hobby lies in the study of any application of high-frequency electricity. The part of the book dealing with wireless telegraphy is thoroughly practical, and consists mainly of a description, rather long-drawn-out, of the making of the author's own apparatus by himself and his boy pupils. Pretty well every detail is treated, but the author's circuits are a little old-fashioned—for example, the receiving circuits have conductive coupling, and inductances are varied by sliding contacts. The "high-frequency" part of the book introduces the reader to the abstract theory of electrical oscillations and waves: "Electricity is a form of energy . . . some form of moving matter," we learn in the first paragraph. Corpuscles, atoms and ether are discussed in a manner that the over-educated reader will quite fail to appreciate. The American atmosphere of the book is very pleasing, and the spelling of "Poulson," "Flemming," "impedence," &c., is very original.

W. H. E.

Direct and Alternating Current Testing. By F. BEDELL, assisted by C. A. PIERCE. (London: Constable & Co.) Pp. x+256. 8s. net.

Few books have been more needed than a comprehensive, and at the same time compendious volume, dealing with the practical testing of electrical machinery on sound scientific lines, and the present volume goes a long way towards satisfying this want. The only point of general criticism is perhaps that it has been written too much from the college laboratory standpoint, and that an attempt has been made to combine theoretical instruction and experiments of educational value with the testing of machines, which has resulted in an insufficient treatment from both sides. But a certain amount of overlap in dealing with these subjects is inevitable, and in a great many cases the practical methods of test can only be understood with direct reference to the assumptions made as to the theory of the machine. One cannot help feeling, however, that a certain amount of the descriptions of the winding and behaviour of machines, which are already to be found in plenty, might have been dispensed with in favour of a short account of the principal instruments and devices used in testing, with some indication of their errors and of the types to be chosen for various purposes.

The book is divided into seven chapters, each containing a certain number of experiments with explanations, notes and references. In the first two, direct-current generators and motors are dealt with, and it is here especially that one would prefer to see the theory curtailed, and a more detailed account of apparatus and methods. For example, on p. 8 the armature resistance of a generator is directed to be taken by fall of potential with the armature stationary, without any hint that with modern machines the resistance so taken may be two or three times that under working conditions, which is, of course, most serious in connection with the losses. On p. 43 there is a slight allusion to the matter when it is stated that no account will be taken of a *possible* difference between the contact resistance under test and working conditions. The direct efficiency test, the Kapp-Housman method of indirect testing, and the Kapp-Hopkinson combined test are all briefly described, but one would have liked to see some practical descriptions of brake tests, of the short-circuit and acceleration methods, and of the analysis of the results of the Hopkinson test.

The remainder of the volume deals with alternating-current testing, and is very interesting. Chapter III. is devoted to alternator characteristics and their predetermination, and the author's clear indication of the distinction between total and leakage inductance, and between armature reaction and leakage reactance, which are so necessary for the appreciation of methods of predetermination. It is satisfactory also to see that the authors, in common with Behrend, avoid wasting time over attempting the accurate prediction of regulation at other than zero power factor, which must remain impracticable in all cases where salient highly saturated poles are employed. Chapter IV. describes some general experiments on series and parallel circuits with alternate currents, preparatory to the testing of other machines; and the experimental determination of the circle diagram for a single resistance reactance combination, which forms an admirable introduction to the various circle diagrams in machines. The following chapter is devoted to transformers, and here again the student must be greatly helped by the process of reducing the even ratio transformer to three or two choking coils, which immediately shows the basis of the no-load and short-circuit tests. In the last two chapters the study of polyphase connections and power measurement, and of polyphase transformers and regulators is dealt with. Induction and commutator motors are not referred to, but the author promises to do this in a later edition.

We have no doubt that the book will be greatly appreciated by many teachers and engineers, and hope that it will soon reach its second edition, and that the authors may find themselves able to give it either a more definitely educational or a more definitely practical aspect.

THE COMMERCIAL SOLUTION OF THE PROBLEM OF UTILISING, FOR THE PRODUCTION OF POWER, THE ENERGY OF SOLAR RADIATION, THE WIND AND OTHER INTERMITTENT NATURAL SOURCES.*

BY R. A. FESSENDEN.

The problem of the commercial utilisation, for the production of power, of the energy of solar radiation, the wind and other intermittent natural sources is a double one. The energy of the sources must first be changed so as to be available in form; it must next be stored so as to be available in time.

Both these problems were solved by me in 1899, but owing to pressure of other work it is only within the past year that the commercially operative plant has been put under construction. The time has, however, not been entirely wasted, as a considerable number of experiments have been made and data obtained which have demonstrated conclusively that the method is a commercial one and applicable on a large scale and under a great variety of conditions.

Details of the operation of the plant above referred to will be furnished in a later Paper, but the results so far obtained justify me, I believe, in publishing a description of the method and of some of the data. It will be noted that the methods employed are extremely simple, and but for the fact that the construction involved is exactly the opposite to that which would naturally suggest itself, they would probably have suggested themselves to others. While the figures given may be subject to some slight modification, they are believed to be substantially correct.

The method of storage will be described first. A storage battery cannot be used. A lead oxide storage battery costs approximately £10 per horse-power hour. Measurements made during the past 10 years show that it is necessary to provide storage capacity for at least two weeks, except under abnormally favourable conditions. The capital cost per horse-power for a storage battery would, therefore, be £140. Taking the interest at 4 per cent., depreciation at 10 per cent. and the upkeep and labour at 5 per cent., the annual cost of storing power with a storage battery would be approximately £26 per horse-power. Doubtless some storage battery companies will claim that these figures are too high, but they are believed to be substantially correct. As, however, 1 H.P. can be produced by a steam plant for not more than £10 per annum it is evident that storage by storage batteries is entirely uncommercial for this purpose.

The method employed is storage by gravity. Two reservoirs are constructed, one at a considerable height above the other, and the water is first pumped up and then allowed to flow down as desired and to actuate a turbine. A cubic yard of water falling through 1,000 ft. is capable of giving out energy equivalent to 1 H.P.-hour.

This is a method of storing power which doubtless occurred to many. There were, however, two practical difficulties in the way. First, if the fall be small, say, 10 ft., the quantity of water used must be very large and the reservoirs must be very expensive. Also the turbines are less efficient. On the other hand, to construct a tower 1,000 ft. high capable of supporting a reservoir of any size would require such a large initial capital outlay and such a large interest and depreciation as to render it impracticable.

For many years these figures appeared to me to act as a bar to the use of gravitation for storage, and I was working along other lines, when one day the idea suggested itself to me of using a negative instead of a positive gravitational potential. That is to say, that the second reservoir should be constructed under ground instead of above ground. The upper reservoir would then lie on a surface of the earth. A shaft would be excavated 1,000 ft. deep, and at the bottom of this shaft, chambers hollowed out and ferro-concreted for the machinery and for the lower reservoir.

Some figures to the effect that the cost of excavating a cubic yard of quartz and bringing it to the surface did not exceed 2s. per cubic yard suggested that the idea was worth looking into. Estimates were obtained from three different firms of mining engineers in Philadelphia which showed that a shaft 1,000 ft. deep could be dug, properly timbered, and the necessary chambers hollowed out at the bottom and ferro-concreted so as to withstand the water-pressure, at a cost not to exceed 8s. per cubic yard, and tenders were made at that price for a 5,000 H.P. plant. Assuming as before, two weeks' storage and an efficiency of 75 per cent., the capital cost per horse-power-hour will be £7. 10s., as against £140 for the storage battery. Assuming interest at 4 per cent. and depreciation at 2 per cent., which latter is a fair value for ferro-concrete work of this character, the total annual cost of the water storage will be approximately 9s., as against £26 in the case of the storage batteries.

As regards efficiency, the water storage has an advantage over the storage battery. The energy efficiency of a storage battery is generally given as 65 per cent.—*i.e.*, approximately 80 per cent. on charge and 80 per cent. on discharge—the current efficiencies on charge and discharge being slightly over 90 per cent.

With the water storage the efficiency of the pumps raising the water may be very high. Figures given in the "Engineer," March 26, 1909, show that pumps lifting 200 ft. may have an efficiency of 97·6 per cent. The efficiency of a water wheel of the Pelton type working at a pressure equivalent to 1,000 ft. is quite high, and such turbines are guaranteed with efficiencies of 91 per cent. This would give an energy efficiency for charge and discharge of 89 per cent., so that the efficiency which I have taken of 80 per cent. is probably conservative. It is probable that as the system comes into extensive use the efficiencies of the turbines will be increased.

Tenders for the pumps and Pelton wheels for a 3,000 H.P. plant show that the cost of this is approximately £2. 10s. per horse-power. Allowing 4 per cent. interest and 4 per cent. depreciation, this makes a total annual cost for pumps and turbines of 4s. per horse-power. The total annual cost of storing 1 H.P. per annum by the negative gravitational method is, therefore, 4s. + 9s. = 13s., as against £26 for storage by storage battery. It will be noted that this figure of 13s. is a conservative one, and might be much higher without rendering the method commercially impracticable.

To consider next the method of obtaining the energy from the sources. There are two main sources available, the solar radiation and the wind. Tidal energy may be neglected as, except in abnormal cases such as that of the Bay of Fundy, the rise is too small to permit of commercial utilisation. There is, however, no reason why, with this method of storage, the tides of the Bay of Fundy should not be utilised, or why some future Commission should not lay out a system of power generation and distribution which shall do for the provinces on the Bay of Fundy what the system laid out by the Ontario Power Commission, of which I had the honour to be the engineering member, has done for the Province of Ontario.

The solar constant is the number of gramme-calories of radiation which would be received from the sun on 1 sq. cm. of area at the earth's surface per minute, the area lying in a plane at right angles to the line joining the earth and sun, if there were no atmospheric absorption. (This is an inconvenient unit, and I have proposed as an alternative unit the number of ergs per second received on the horizontal surface of 1 sq. cm. The usual unit is, however, used here.) This value of the solar constant is equivalent to about 150 ft.-lb. per square foot per second. On an area 100 metres square the total power received will be approximately 20,000 kw.

This figure, however, is to be reduced for four different reasons. First, because the Langley value of the solar constant is probably too high; it would appear that 2 calories is more nearly correct. Secondly, because on account of the atmospheric absorption the number of gramme-calories actually available at the surface of the earth is less than the solar constant. Thirdly, because the actual absorbing area seldom or never faces directly to the sun, on account of its latitude and the rotation of the earth. Fourthly, on account of clouds.

The only safe way, therefore, is to take an actual location and measure the actual amount of radiation received during the entire time for a number of years.

Unfortunately until recently no reliable automatic recording apparatus was available. I have, however, recently obtained a number of such recorders from the Cambridge Scientific Instrument Co., and these are being set up at different points, and will undoubtedly give very valuable information.

Meantime, in order to obtain the necessary data, a former assistant of mine, Prof. Very, whose work in connection with Prof. Langley and whose own researches are well known to all physicists, was kind enough some years ago to investigate the matter for me. As the result of his investigations he found that for Central Europe, averaging a number of entire years, the number of gramme-calories per annum received on a surface of 1 sq. cm. varied between 37,000 and 54,000, the variation being due to the variation in the amount of annual cloudiness. For the Northern United States he found the values to vary between 42,000 and 65,000. For the arid South-western States he found a value of approximately 100,000. Reducing this to kilowatt-hours, we obtain the following values for the amount of solar energy received on an area 100 metres square per annum at the earth's surface:—

Central Europe	4,000,000 to 6,000,000	kw.-hours
Northern U.S.	5,000,000 to 7,500,000	,,
South-western U.S.	10,000,000 to 15,000,000	,,

i.e., the average is only from 4 to 10 per cent. of the maximum radiation.

As regards the amount of power to be derived from the wind, I have a steel tower at Brant Rock, Mass., 420 ft. high, erected in 1905.

* Paper read before Section G of the British Association at Sheffield.

Digitized by Google

My tests show that a windmill 300 ft. in diameter is capable of delivering on an average during the entire year 800 H.P. on the shaft. By a windmill 300 ft. in diameter I mean either a single wheel or, what would probably be more efficient and cheaper, a number of smaller windmills mounted in a steel frame and revolvable on a circular track so as always to face the wind. These figures are approximately 30 per cent. higher than those obtained by the Danish experimenters, but I attribute this to the fact that the amount of power available increases quite rapidly with the height, and the Danish experiments were made at levels nearer the surface of the ground.

The method of utilising the power of the wind is very simple. A number of steel rope drives run from each of the small windmills mounted in the frame to the main shaft which has its bearings fastened to the frame so that when the frame is turned round to face the wind the main shaft moves with it. The main shaft drives the pump, the pump rod being revolvable as the axis is shifted in position. The Pelton wheel drives the dynamo. The Pelton wheel may also be driven directly by a rope drive from the main shaft of the windmill, the Pelton wheel being disconnected, or left connected.

To utilise solar radiation, a solar tank is used containing water which is heated until the steam reaches approximately the pressure of the atmosphere. The steam so generated at atmospheric pressure drives a low-pressure steam turbine or a special type of engine, which will be described in another Paper. The turbine operates the pump. From Provost's law it should be possible by solar radiation to raise the temperature of the water to 473 deg. absolute, though I am not aware that this temperature has ever actually been reached.

To attempt this would, however, be impracticable for a number of reasons, and the working would be irregular. In addition the pressure of the steam would be such as to necessitate a strong containing chamber for the working fluid. As the result of experiments it was found best to sacrifice a certain amount of thermo-dynamic efficiency for practical reasons. A working temperature of 100° C. was chosen, because with the steam at atmospheric pressure the transparent top of the chamber containing the working fluid could be made very thin and would not have to withstand any pressure. The pressure of the steam is automatically kept very slightly above atmospheric pressure in order to prevent any air leaking into the condenser. The transparent roof is of double thickness, and contains wire netting embedded in the glass as a protection against hail. The supports for the glass are made of wood and no special attempt is made to render them tight. The working fluid flows in a thin stream across the bottom of the solar tank, and the thickness of the stream is varied automatically with the amount of radiation received.

The working fluid contains a small amount of bichromate of potash. The glass forming the transparent covering contains a small amount of sulphate of iron, sufficient to give it a pronounced greenish tinge. It has been found that by this means the glass can be made metallicly reflecting for wave-lengths corresponding approximately to those emitted by the heated water, while remaining fairly transparent to the radiation from the sun. The solar tank is made to have as little specific heat as possible, and, what is more important, to be protected from convection and conduction losses. The thermodynamic efficiency of the system is approximately 15 per cent., and it is anticipated that approximately 10 per cent. will be obtainable on the shaft of the steam turbine.

From tenders made the costs per horse-power have been found to be approximately as follows:—

Solar tank	£2
Low-pressure steam turbine and condenser	5
Dynamo	3

Adding to this the cost of the pumps and Pelton wheel, we obtain a total of £12. 10s. for the first cost per horse-power for the machinery exclusive of the reservoirs. Allowing interest at 4 per cent. and depreciation at 4 per cent. and 2 per cent. for labour, we obtain a value of £1. 5s. per annum per horse-power-hour as the cost, exclusive of the reservoirs. Adding the cost per horse-power of the reservoirs we obtain a total of £20 for first cost and £1. 14s. as the annual cost per horse-power.

It will be seen that these figures compare quite favourably with the present cost of producing power from coal. Moreover, these figures are too high, for the reason that it is proposed to operate a windmill plant in conjunction with each solar radiation plant. The load will be greatly evened up, and a much better all-day and all-year efficiency obtained, because the wind is, as a rule, most effective during cloudy weather and at night time—*i.e.*, at the time when the solar radiation plant will nor be operating. Not only will the storage plant with its accessories be smaller for a given output of power, but in addition the steam pumps and turbines and storage reservoirs employed for the solar radiation method will be available without additional cost for the wind method.

Assuming a solar tank covering an area of 200 metres square we may expect to receive a total radiation of approximately 20,000,000 (20 million) kw.-hours per annum. Assuming an efficiency of 10 per cent. we should get 2,000,000 kw.-hours on the steam turbine shaft. Assuming a seven-hour day, we would get an average of 800 H.P. of power from the solar radiation plant. Adding to this the energy derivable from the windmill we obtain a total of approximately 1,500 H.P. The total cost of generating and storing this power will be in the neighbourhood of £1. 10s. per annum.

It is hoped that an opportunity will be afforded at a later date of giving the exact figures obtained in practice from the 3,000 H.P. plant. In the meantime, however, it is believed that the present communication will be of interest as showing that for many classes of work the problem of obtaining power from intermittent natural sources has been solved.

The figures given above are for average conditions. The location of the first plant is, however, much more favourable. It is situated at a copper mine, where the vertical shaft is already available and where worked out lateral chambers are available for the lower reservoir, and a portion of the pumping machinery is also available.

In addition the average solar radiation has rather more than twice the value taken above. Also the cost of producing the power from steam is considerably higher than the average on account of the difficulties of transportation and the high price of coal.

The following is a comparison between the cost of producing 1 H.P. for a year by steam, gas engine, water-power at Niagara Falls and by the present method. The estimates are based on a plant having a capacity of 100,000 H.P., and operating under average conditions.

The estimates for the costs of steam and gas-engine power have been prepared from data gathered in connection with the preparation of the plants for a number of power propositions during the past 20 years. The data for the cost of producing power at Niagara Falls was obtained in connection with my work as Technical Commissioner for the Ontario Power Commission. The data for the cost of obtaining power from intermittent natural sources was obtained by substituting for the values of the machinery necessary for the 3,000 H.P. plant above referred to the values which these items would have in the case of 100,000 H.P plant.

Method of generating power.	Cost per H.P. per year.
Steam	£3 0 0
Gas engine	2 0 0
Water-power at Niagara Falls	0 15 0
From intermittent natural sources	0 18 0
Water-power, exceptionally favourable conditions	0 10 0

It will be seen that while this method of producing power is much cheaper than those of steam or gas engine, it is approximately the same as that of water power under fairly favourable conditions, such as at Niagara Falls. This is because in the present method and with water power the capital first cost is the determining factor. The capital first cost per horse-power by the present method using a solar tank alone is approximately £12. 10s., and using windmills in conjunction with the solar tank approximately £9. The capital first cost at Niagara Falls is approximately £8.

The present method gains chiefly from the higher fall and from the cheaper and more efficient water motor, also from the fact that only one-seventh as much water has to be handled, and there are no dams to build or large buildings to erect. It loses from the fact that a pump has to be supplied, also a steam turbine and solar tank or windmill. The method, therefore, will not be of so much value in places favourably situated for obtaining water power. Localities so favoured are, however, comparatively few in number.

In addition, under exceptionally favourable conditions, such as when used in conjunction with mines, the cost of the present method may be considerably less than 18s.

For example, England is not well situated for the use of the solar radiation method. But the average wind value is fairly high, and the coast is lined with high cliffs. A rough estimate shows that by excavating reservoirs on the top of the cliffs, mounting windmills there, pumping the water up from the sea to the upper reservoirs and letting it run back through turbines and dynamos placed on the beach, that the cost would be considerably lower than that given above. Also that by this means more than sufficient power can be generated to supply all the factories, lighting plants and railroads in Great Britain. There will be no difficulty about distributing the power, as where the amount of power is sufficiently large, voltages of 500,000 can be used efficiently, safely and cheaply.

The method is, of course, not applicable for water transportation.

A thorough investigation into the possibilities of storage made a number of years ago showed that no electric-chemical method of storing energy could possibly compare as regards weight and first cost with the use of a hydro-carbon such as alcohol in a gas engine. Investigations as to the cost of producing alcohol from bananas and

Digitized by Google

other tropical fruits show that with the manufacture conducted on a sufficiently large scale, alcohol can compete very favourably with petroleum and petrol at their present prices.

It is not without the bounds of possibility that this industry may be developed into an exceedingly profitable one, and that the West Indian islands may regain the position which they occupied at the time when they were the chief producers of sugar.

MAGNETIC HYSTERESIS IN A ROTATING FIELD.*

BY M. G. LLOYD.

Many investigators have studied the phenomenon of hysteresis, using magnetising fields which could be increased or decreased by steps, or else using fields which rapidly reverse in direction, as produced by an alternating current. The most notable results are those of Ewing and of Steinmetz. The latter established the approximate relation $W = nZVB^{1.6}$, where V is the volume, B is the maximum flux density and W the power transformed when the frequency is n cycles per second. Z is a constant depending upon the material used. This formula holds fairly well for iron and steel through the range of flux density used mostly in industrial applications, but it does not hold for very high or low flux densities, and the exponent is seldom exactly 1·6 even in moderate fields, but varies for different specimens.

If instead of using a field which simply alternates in direction we subject the magnetic specimen to a rotating field, such as may be produced by polyphase currents, there is again a lag of magnetisation behind the magnetising field, but the lag is a lag in direction, not in magnitude. This rotary hysteresis requires an expenditure of

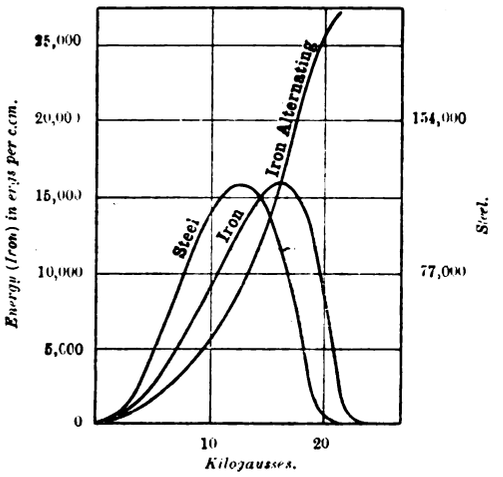

FIG. 1.—ROTARY HYSTERESIS FOR IRON AND STEEL.

energy, as in the other case, but the amount of energy transformed is not the same. Eddy currents are produced in both cases, and aid the transformation of energy into heat; but the two sources of energy loss can be distinguished by taking observations at two different frequencies.

The hysteresis in a rotating field was first observed by Baily, who showed, in 1894, by rotating a magnet about an iron armature and measuring the torque, that the hysteresis increased with the flux density in moderate fields, but finally reached a maximum and decreased to zero when the field was made sufficiently intense. This result was obtained with both soft iron and hard steel, and was a confirmation of Ewing's theory. Beattie made similar experiments upon nickel and cobalt, with similar results. In nickel, a maximum hysteresis loss of nealy 10,000 ergs per cubic centimetre per cycle was observed with a magnetising field of 340 gausses. In cobalt a maximum of about 36,000 ergs per cubic centimetre per cycle was observed, and in both cases the plotted curves indicated that the hysteresis would reach zero if the flux were carried to the saturation value. Beattie and Clinker found that for iron the hysteresis reached a maximum for a flux density of 16,000 gausses, and then decreased, reaching zero at about 25,000 gausses. Schenkel experimented by rotating the specimen in a steady field, and measured the torque by a form of transmission dynamometer. His results were similar to the above. Grau and Hiecke found a maximum hysteresis in iron at a flux density of 13,600 gausses.

In 1908 Weiss and Planer conducted some experiments with a rotating magnet which were somewhat more refined than the previous work. The specimens were in the form of discs, and when placed horizontally were subjected to a rotating field, but when placed vertically the effect was the same as an alternating field. Observations were made upon steel, iron, nickel and pyrrhotite. They found, like previous observers, that for low fields the hysteresis was greater in the rotary field than in the alternating, but after passing a maximum the hysteresis in the rotating field finally decreased to zero, as the material reached saturation. Fig. 1 shows some of their results. The ratio of rotary to alternating hysteresis was found to be largest for the weakest fields, and had a value of 3·6 for nickel.

During the past year two researches have appeared showing the variation of rotary hysteresis with temperature. Fuller and Grace used two-phase alternating current to produce the rotary field, while Perrier used apparatus similar to that of Weiss and Planer. Both used electric heating coils to obtain the higher temperatures. Both sets of experiments show that the maximum hysteresis in the rotary field decreases with increasing temperature, and that this maximum is reached with a lower flux density. Thus for iron at 580 deg. this maximum occurs at 10,500 gausses, while at temperatures below 340 deg. it occurs at about 16,000 gausses. Since the saturation value is also reduced by increasing the temperature, it was to be expected that the hysteresis would decrease to zero for a lower magnetisation, and this was found to be the case.

Perrier worked with nickel, magnetite and three kinds of iron, and concluded that the ratio of the maximum values of the two kinds of hysteresis was characteristic of the material and independent of the temperature.

In some recent experiments Herrmann has adopted a different method of measuring the energy and gets results entirely different

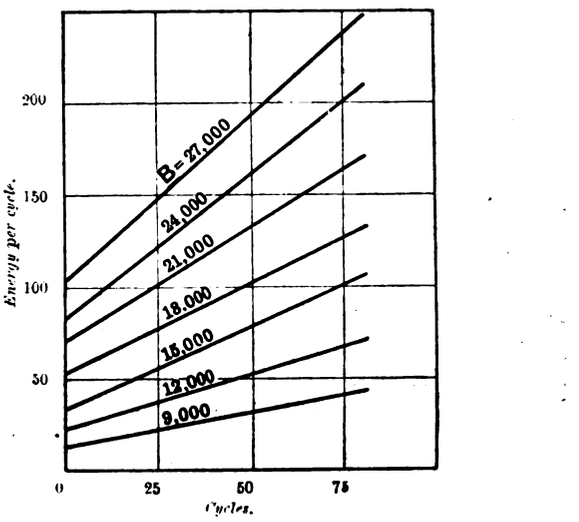

FIG. 2.—ENERGY PER CYCLE.

from previous observers. By means of a thermo-couple he observes the rise of temperature in the specimen in a given time, usually 15 minutes, and takes this as a measure of the energy expended due to hysteresis and eddy currents. He does not claim high quantitative accuracy for this method, but insists that it would indicate a maximum and a later lowering of the curve if such existed. No maximum, however, is evident in his curves. In Fig. 2 the energy per cycle is taken as ordinate, and the separation of hysteresis and eddy current losses thereby effected. The intersection of each curve with the vertical axis gives the hysteresis for that particular flux density, and these intercepts are seen to increase with the flux density up to 27,000 gausses, the highest value employed. He concludes that the hysteresis in a rotary field is therefore no different from the hysteresis in an alternating field.

* Abstract of an article in the "Electrical Review and Western Electrician."

CORRESPONDENCE.

THE PRICE OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am very glad to read in your present issue that you welcome my Paper on the above subject.

I entirely agree with Mr. Pearce that the interpretation of right principle in the form of practical tariffs is a process hedged about with many difficulties. To have got rid of error in our conception of principles is, perhaps, to have won less than half the battle, but it is a step, and not only a step, but a necessary step. I do not propose now to travel beyond

Digitized by Google

it, because I fear that doing so would almost certainly obscure this essential preliminary, and also because there are so many who are much better equipped than I can be for dealing with that part of the problem.

I am writing this letter in order to question the wisdom of regarding electricity supply as a "by-product" supply in regard to any of its uses. I am sorry that my Paper evidently conveys the impression that I so regard it, but my use of various "by-product" examples was intended to expose the fact that "demand" could be a very potent factor of price, so great indeed, as entirely to swamp the "cost" factor. It is true that I point out, incidentally, that electricity supply has something in common with such jointly-produced commodities. A restricted-hour demand is, in a sense, a demand for a by-product, but my Paper does not deal, excepting incidentally, with that aspect of electricity supply. On page 7 of the Paper I expressly limit the application of the conception of "joint" production to variations in demand "in respect to time" in the case of electricity supply. I desire to see engineers anxious and ready to seize an opportunity, the circumstances of nature has placed in their hands, viz., that of utilising the fact that electricity is in demand for different purposes as the means adapting or adjusting supply to the varying intensity of demand as expressed by the varying market prices of the different uses of electricity.

My diagram, No. 2, exhibits, I think, the beneficent effect of that process to all concerned. I accept your distinction between the production of beef and hides, and of electricity, and I should like to emphasise it. I think that it will be safer to clear the mind of the conception that the dividing up of electricity supply into different classes of supply, some of which may be considered as by-produced relatively to others, is equivalent to the production of gas and coke or of beef and hides. It is better, I think, to confine that conception to such divisions as are represented by a "restricted-hour" demand, &c., and to picture the dividing up of supply into different classes, according to the different uses of electricity, as simply a means of gaining the advantage of adaptation of supply to demand, through the operation of corresponding "classified" tariffs.—I am, &c.,

EDW. W. COWAN.

4, Queen Victoria-street, Sept. 12.

ON METALLIC RADIUM.*

BY MME. P. CURIE AND A. DEBIERNE.

In order to obtain metallic radium we employed the methods described by M. Guntz for the preparation of barium. Some preliminary experiments were, in fact, made on barium with a very small quantity of matter (about 0·1 gramme), thus rendering the operations very delicate. These experiments enabled us to determine the method which should be used in the preparation of radium.

The principle of the method consisted in preparing an amalgam and in expelling the mercury by distillation under favourable conditions. The amalgam was obtained by the electrolysis of a perfectly pure solution of radium chloride, with an atomic weight of 226·5, a mercury cathode and platinum-iridium anode being used. The amount of salt employed was 0·0085 gramme. This amalgam decomposes in water and alters very quickly in air. It was quite liquid; while under the same conditions we obtained an amalgam of barium containing numerous crystals. The dry amalgam was quickly placed in an iron boat, which had been previously reduced in pure hydrogen. This boat was placed in a quartz tube, and a vacuum created inside the apparatus.

The distillation of the mercury was a very delicate operation. It should be carried out without ebullition being allowed to occur even momentarily. The distillation was finally made in pure hydrogen, the pressure of the gas being always higher than the pressure of the saturated mercury vapour at the temperature of the boat. This temperature was determined by means of a thermo-electric couple whose junction was fixed in the metal of the boat.

Owing to the small quantity of matter on which we worked, we particularly required pure hydrogen for the operation. We noticed that hydrogen which had been purified or dried by the ordinary means might still alter the amalgam. In order to obtain further purification, therefore, the hydrogen was admitted into the apparatus through a platinum tube, which was heated to a high temperature in the electric furnace. This method of purification seemed to leave nothing to be desired.
